Although successful kidney transplants took place as early as the 1950s, it was not until the 1970s that immunosuppressive drugs made it possible to transplant kidneys between people who were not immediate family members. The idea of kidneys for sale, which had been around for several decades as an ethical conundrum, was now a reality. The first known kidney-selling network to come to light was in the early 1980s in India, where brokers arranged for patients from Oman and the United Arab Emirates suffering from end-stage renal disease to be flown to Bombay, where they would be given kidneys donated by poor Indians who were paid approximately \$3,000 for their trouble. The long-term health results for both donors and recipients were poor, but the practice spread nonetheless. In 1988 a prominent London nephrologist was discovered to be recruiting patients from rural Turkey and flying them to Britain, where their kidneys were sold to paying patients from Greece, Afghanistan, Libya, and Israel. By the 1990s the kidney trade was known to exist in South Africa, Turkey, parts of the former Soviet Union, and China. China was unique in that the kidney trade there was a state-sanctioned enterprise in which organs were removed from executed prisoners and sold to overseas patients.

—Joel Tannenbaum

handguns, or adulterated foods or medicines could be considered bads. Only some bads are illegal.

Nearly all of these black market commodities are controlled by organized criminal networks. These seem to exist in all times in all societies, but often access to a particularly lucrative global black market will allow a criminal network to gain access to considerable political and economic power, particularly if they operate within countries whose governments are structurally weak or unstable. This was the case with many criminal organizations in former Warsaw Pact and Soviet countries after the end of the Cold War. Their involvement in, among other things, sex trafficking and the massive international trade in stolen automobiles allowed many of them

to exercise influence at the highest levels of government.

To further complicate matters, the purveyors of black market commodities are sometimes the states themselves. Sometimes the state is a comparatively strong state, wishing to advance short-term political or economic objectives usually far from home. This was the case with the involvement of U.S. intelligence services in the heroin trade in Southeast Asia during the Vietnam War. Sometimes the state is a comparatively weak state, desperate for hard currency. This has been the case with North Korea's active participation in the production and distribution of counterfeit U.S. dollars and with the illegal export of caviar from former Soviet countries in Central Asia.

Global black markets in human beings come in multiple forms, but the two most important are the trafficking of sex workers and the trafficking of illegal migrant workers. There is obvious overlap between these two categories, but they remain distinct in that the former have often been kidnapped and essentially imprisoned in their new environs. This was the case with women in Bulgaria and other former Soviet countries who were lured with promises of legitimate work in Western Europe only to find themselves forced into sex work and with Nepali women who found themselves in neighboring India under similar circumstances. In the case of illegal immigration, the victims often wish to migrate but are unable to do so through legal means and instead are forced to trade their fu-

ture labor for illegal and often dangerous passage to their new country, where their illegal status generally places them outside the protection of the law. This has often been the case with human trafficking between southern China and major urban centers in the United States.

To make matters yet more complicated, the distinction between organized criminal networks and states themselves has often been an ambiguous one. Kimtex, a Bulgarian company run by the security services of the government during the Cold War, specialized in weapons sales in the Middle East and Africa but dabbled in drugs and human trafficking as well. When private enterprise was legalized in Bulgaria in 1986, 90 percent of the joint-stock companies established belonged to members of the security services.

The broad economic trends of the post-Cold War world such as privatization and relaxed trade laws, whether their legacy is ultimately deemed positive or negative, have created an environment in which global black markets have not only survived but thrived.

War and Diplomacy

The Atlantic Charter, devised by British prime minister Winston Churchill and U.S. president Franklin Delano Roosevelt in 1941 in the midst of World War II, outlined a common set of principles to devise an international set of organizations to regulate world diplomacy and ensure global stability in the postwar world. Following the war that had led to an estimated 60 million deaths, optimism prevailed that the promises established by the Atlantic Charter could be realized through the cooperation of the Grand Alliance (the United States, Britain, and the Soviet Union). Yet fissures preventing such an eventuality were already apparent at conferences held at Yalta and Potsdam in 1945, when the Allies divided up Europe into spheres of influences, with the Soviet Union holding onto most of Eastern Europe and the United States extending its influence across Western Europe. The Marshall Plan of 1947, the Berlin Airlift of 1948, and major differences over postwar Germany ignited the nascent Cold War between the superpowers.

The ideologically driven Cold War that erupted between the United States and the Soviet Union in the postwar period did not result in World War III. The development of new weapons of mass destruction eclipsing the nightmare potential of even such conventional warfare as seen during World War II helped limit the superpowers' engagement to diplomatic offensives and proxy wars, including wars that emerged from anticolonial struggles.

The Cold War had a powerful influence on such wars of national liberation. These efforts grew in part from the anticolonial sentiment (and rhetoric) shared by the United States, the Soviet Union, and the United Nations (UN). Long-standing indigenous resistance to colonization gained force against the European colonial powers that World War II had left weakened militarily and economically. Many of these nationalist struggles turned into proxy wars for the superpowers. Postwar regional conflicts, such as the India-Pakistan Wars (1947, 1965, and 1971), the Arab-Israeli Wars (1948, 1967, and 1973), the Algerian War (1954–1962) against France, civil wars in the Congo (1960–1962, 1996–1997, and 1998–2003), and the Angolan Civil War (1975–2002), not to mention myriad wars in Latin America—Cuba (1959), Guatemala (1960–1996), and El Salvador (1980–1992)—were subsumed in the greater Cold War conflict. Regional actors chose sides for the benefit of funds and weapons. Other nationalist liberation struggles, such as those in Vietnam and Afghanistan, brought direct superpower military deployment, as these regions were seen as vital links in the fight against an ideological adversary. However, U.S. involvement in the Vietnam War (1964–1975) and the later Soviet-Afghan War (1979–1989) turned into

quagmires for each superpower, as the unpopular wars consumed troops and money and severely marred international prestige and domestic morale. Furthermore, U.S. support of authoritarian regimes in Nicaragua, South Korea, South Vietnam, Iran, and Chile marred its international reputation as the beacon of democracy, particularly as these states practiced state terrorism against internal dissidents. Some major nationalist struggles did not neatly fit the Cold War context. The Iranian Revolution of 1979, led by Islamic fundamentalists against American support of the shah, did not fit the mold of Cold War ideological rivalries. In this case, there was no Soviet support for the new Iranian regime, as a reactionary ideological position was enunciated that rejected both U.S. and Soviet paradigms.

Despite the efforts of the United States and the Soviet Union to garner support from their domestic populations and their allies, support often shifted and foundered. Chinese accusations of Soviet revisionism, for example, partly due to Nikita Khrushchev's policy of peaceful co-existence, did much to taint Soviet efforts abroad and accentuate Chinese leadership of the global liberation movements. Critics were not

Groups such as the Red Brigades in Italy and the Red Army Faction in West Germany used violent tactics in their efforts to destroy the establishment. Some of the more violent groups found common cause with Third World liberation movements, often training and funding their causes.

only abroad but also at home. In the Soviet Union intellectuals who voiced a dissident position (often circulated in the underground samizdat literature) were often jailed or otherwise persecuted. The antiwar and antinuclear movements in the West, in tandem with the counterculture of the late 1960s and early 1970s, led to widespread protests and sometimes violent government reactions. Groups such as the Red Brigades in Italy and the Red Army Faction in West Germany used violent tactics in their efforts to destroy the establish-

ment. Some of the more violent groups found common cause with Third World liberation movements, often training and funding their causes.

The end of the Cold War in 1991, which was expected to herald permanent peace, in fact exposed a new instability. Suddenly the world's sole superpower, the United States, sought to find a new role amid the chaos unleashed by the fall of the Berlin Wall. As the regimes that had held contentious populations together under communist ideology fell apart, such as in Yugoslavia, new nationalist hatreds surfaced among the region's myriad ethnic groups. Ethnic cleansing was unleashed against minority populations in states such as Bosnia-Herzegovina. Ethnic cleansing also developed in other unstable states—for example, in Rwanda and in the Darfur region in the Sudan—as groups within these African states sought to create a more homogenous population to conform to state boundaries. U.S. support of Israel and an international military presence in the Middle East following the first Gulf War (1990–1991) increasingly fueled anti-American sentiment in the region. Such resentment would see its ultimate consequence with the September 11, 2001, attacks on the World Trade Center and the Pentagon, thereby unleashing a new era in global war and diplomacy.

Although they became increasingly important after the September 11 attacks, terrorist groups and asymmetrical warfare had characterized conflicts preceding and during the Cold War as well. In the earlier period, groups such as the Irish Republican Army, the Basque ETA, the Red Army Faction, Hamas, and Hizbullah waged asymmetrical wars against organized state military institutions. Such terror groups long had functioned as nonstate actors, working as international organizations with interlinking autonomous cells. Suffused with ideological fervor as well as international funding from sympathetic contributors, these groups used simple technologies to impart terror on civilian populations and draw attention toward their cause. Al-Qaeda's attacks on September 11, 2001, were such an event, on a far vaster scale. Subsequent attacks in Madrid and London showed the vulnerability of Western societies to such organizations and their methods. Moreover, drug cartels in Colombia and more recently Mexico openly have engaged in war against their respective states, illustrating how nonstate actors may successfully vie with state military institutions.

In 2009, two decades after the fall of the Berlin Wall at which point the so-called end of history was in sight, the world is still engulfed in warfare. Currently, the United States is engaged in wars in Iraq and Afghanistan, not to mention a declared global war against Islamic terror networks. As evidenced in the Russo-Georgian Conflict of 2008, Russia has continued to extend its influence in Central Asia and the Caucasus region, often at the expense of its smaller neighbors. Regional conflicts in Congo, Sudan, and Sri Lanka continue in addition to the territorial disputes between Israel and Palestine and between India and Pakistan. Nuclear proliferation continues to be an issue, with new nations becoming unbidden members of the nuclear club. While no catastrophes on the scale of the world wars of the first half of the twentieth century have occurred, the human population has continued to experience instances of war, widespread destruction, civilian deaths, and genocide.

—*Abraham O. Mendoza and Fred Nadis*

■ Introduction: Cold War Conflicts

While both the Berlin (1961) and Cuban Missile (1962) crises nearly brought both superpowers to a direct nuclear confrontation, the fear of nuclear war forced the United States and the Soviet Union to seek other venues for confronting each other. Regional contentions such as the Arab-Israeli conflict, the India-Pakistan wars, and wars of national liberation (e.g., Vietnam, Algeria, and Angola) were supported by both the Soviet Union and the United States, albeit on opposing sides. However, whether disputes over territory or national lib-

eration struggles, these were fought in a Cold War context, with the superpowers offering differing levels of financial, military, and intelligence backing. Rarer, direct intervention on the part of the superpowers, in the form of combat troops (the United States in Korea and Vietnam, and the Soviet Union in Afghanistan) created theaters of operations where the superpowers again confronted each other indirectly and thereby minimized the potential for the outbreak of nuclear war. Nonetheless, such direct interventions, specifically Vietnam and Afghanistan, were a drain

GLOBAL DIVISIONS AT THE HEIGHT OF THE COLD WAR, 1962

on the finances of the superpowers in addition to being costly wars of attrition that depleted combat troops through heavy casualties and severely affected the superpowers' prestige internationally. While many of these regional conflicts would have occurred anyway, nonetheless Cold War considerations prompted the attention of both the United States and the Soviet Union's policy makers, who attempted to influence these conflicts and fit them into their own ideological and geopolitical goals.

Communist Insurgencies

Also called wars of national liberation, or people's wars, these communist revolutions became most apparent and prominent in the post-World War II era when the defeat of international fascism (the avowed enemy of communism) and the exhaustion of the Western imperial powers (Great Britain, France, and the Netherlands, among others) provided the communist forces headed by the Union of Soviet Socialist Republics (USSR), or Soviet Union, an opportunity to operate with far less resistance. The combination of Soviet designs—later Chinese communist designs—and anticolonial sentiment influenced both the impetus and the character of these revolutionary struggles. Global changes socially and politically that included indigenous unrest, rising nationalism, increased access to military technology, and development and refinement of guerrilla warfare created yet further advantages for communists and their adaptation to local political conditions.

Throughout the postwar era, insurgencies developed on nearly every populated continent of the globe to varying degrees: Europe, Asia, Africa, Central and South America, and the Middle East. Communists such as Mao Zedong (China), Fidel Castro (Cuba), Ernesto "Che" Guevara (Latin America), Ho Chi Minh (Vietnam), and Pol Pot (Cambodia) became associated not only with the leadership of these movements but also with some of the major historical events of the modern era. Although each communist guerrilla war differed in some aspects and demonstrated a remarkable adaptation to local and historical circumstances, all of these revolutions had the

basic aim of overthrowing the capitalist or feudal systems of their respective countries, imposing a communist dictatorship of the proletariat, developing an economic and social system along communist lines, and working toward the betterment of international communism policies of Marxism-Leninism. These insurgencies posed a major obstacle to the foreign policies of the United States and other countries of the free world and likewise played a major part in the developments of the Cold War era.

Early successes of communist revolutions in Russia and later China propelled the revolutionary socialist movement forward and added leadership, support, and inspiration to communist insurgencies around the globe. In 1919 the Russian Bolsheviks, led by Vladimir I. Lenin, overthrew the tsarist system of imperial Russia and transformed the communist movement from an ideological following of disorganized adherents to a highly organized state-supported movement with the entire resources and experiences of the Soviet Union. Lenin not only established the Communist International (Comintern) as a guiding, unifying, and supportive organization to further international communism, but he and his associates also particularly singled out the colonial regions of the world for communist insurgencies.

In China, Mao followed Lenin's example but added important additions to the prevailing ideology of Marxism-Leninism. Rather than relying on the proletariat as the basis of revolution, Mao relied on the rural peasantry for developing communications, organizational structures, logistics, and resistance. He developed a three-staged guerrilla warfare strategy that utilized the strength of the peasantry to offset the power of the urban areas, which then were held by the Nationalist forces of Jiang Jieshi (Chiang Kai-shek). Mao summarized his guerrilla warfare strategy by asserting that when the enemy advances the insurgents retreat; when the enemy camps, the insurgents harass; when the enemy tires, the insurgents attack; and when the enemy retreats, the insurgents pursue. His victory over Jiang in 1949, after decades of resistance, emboldened communist revolutionaries around the world. Mao's victory and tactics provided an effective framework for organizing and conducting guerrilla wars in East Asia and developing countries,

➤ KHMER ROUGE

The Khmer Rouge was an armed communist organization that ruled Cambodia between 1975 and 1979 and endorsed a revolutionary strategy aimed at returning Cambodia to an idealized agrarian past. Their policies, however, led to their committing mass murder on a genocidal scale.

After World War II, Cambodia's nationalists sought to end French colonial rule; many left-wing activists came under Vietnamese communist influence. After 1950 the resistance movement split, and the anti-Vietnamese element, popularly known as the Khmer Rouge, coalesced around a group of ethnic Khmer intellectuals who emphasized Cambodia's history as a regional power. This group was led by Saloth Sar (after 1969 he was known as Pol Pot), a French-educated revolutionist greatly influenced by the writings of China's communist leader Mao Zedong.

Pol Pot shifted the Khmer Rouge's focus from urban-based activism to rural-based armed insurgency. In April 1967 in Battambang Province his Communist Party of Kampuchea (an ancient name for Cambodia) staged an uprising against local officials of Cambodia's government, led by Prince Norodom Sihanouk. The revolt was quelled, but subsequent punitive raids against the communists kindled growing support among Cambodia's poorest peasants. The Khmer Rouge military grew rapidly and in April 1975 overthrew the government of General Lon Nol, who had replaced Sihanouk.

Over the next three years the Khmer Rouge, known to Cambodians as Angkar (Organization), brutally tortured and killed tens of thousands of technicians, teachers, and specialists in all fields from dance to development economics. Agricultural production dropped, and food shortages caused further devastation. An estimated 1.5 million people, approximately 20 percent of Cambodia's population, died under Khmer Rouge rule, which ended when Vietnamese troops invaded Cambodia in 1979. Remnants of the Khmer Rouge maintained a low-level insurgency in western Cambodia until 2000. Pol Pot died while under house arrest in 1998. Cambodian courts continue to prosecute other Khmer Rouge leaders.

—Laura M. Calkins

With a skull on the muzzle of his M-16 rifle from the killing fields, a Khmer Rouge government soldier waits with his comrades for the word to move out from Dei Kraham, 20 kilometers south of Phnom Penh, during an operation along Highway 2, September 5, 1973. (Bettmann/Corbis)

and communist China provided critical bases and training areas for Marxist-Leninist revolutions in Southeast Asia, including the revolution led by a charismatic communist Ho Chi Minh, who fought successfully against both France and later the United States. Moreover, during the same period nearly every nation in Southeast Asia faced a serious proxy war led by leaders who lifted up the so-called Red banner: Malaysia, the Philippines, Cambodia, Thailand, Burma, and Indonesia.

During the 1960s, 1970s, and 1980s, communist revolutions spread throughout Latin America, Africa, and the Middle East, an indication that communism found fertile political ground in the anticolonial struggles of the era. Castro and Guevara led the revolution in Cuba and promoted insurgencies in other parts of Central and South America. Cuban troops operating in Angola and Ethiopia, supporting communist regimes there, demonstrated both the internationalism of the movement and its solidarity with other communist insurgencies. Other African states, such as South Africa, demonstrated that their revolutionary movements had been influenced by communist ideology. Although the Middle East was also a theater for communist insurgencies, the results were far less successful, as many Muslims rejected the materialistic and atheistic notions of communist ideology.

In the early 1990s the collapse of the Soviet Union furthered the already declining position of international communism. With the loss of Soviet support and the transition of China from communism to capitalism, communist insurgencies withered on the vine as the entire movement fell into obscurity. Although communist insurgencies exist today in Nepal and the Philippines and although the communist parties of the world remain active, their political power, popular appeal, and military capacity are negligible in comparison to their earlier periods of success. Contrary to popular opinion in the United States and elsewhere, communist insurgencies were not invincible. During the Cold War period, popular and government forces defeated the communists in Malaysia, the Philippines, El Salvador, Singapore, Indonesia, and numerous other places around the globe.

Cold War in the Middle East

The Cold War began with most of the Middle East controlled directly or indirectly by the United Kingdom and France, with a strong U.S. presence. As elsewhere, the region became a pawn in the Cold War. By the early 1960s the West European empires no longer existed, and the United States and the Soviet Union were the major players in the region, vying for influence over and control of resources and strategic locations. Yet the countries in the Middle East were often able to use this competition to their benefit by bidding for economic, political, and military support. They did this by allying with the highest bidder, changing sides as circumstances warranted, or advocating neutrality as a means of presenting the world an alternative to superpower domination.

In 1946, Iran became the first major Cold War hotspot in the Middle East. Even before the end of the war the Soviet Union had backed the leftist Tudeh party, which supported Iranian oil concessions to the Soviets. The Soviets controlled much of northern Iran and after the war supported establishment of communist republics there. While both Britain and the United States withdrew their forces from Iran after the war, the Soviets remained, preventing Iran from reestablishing control of all of its territory and demanding oil concessions in return for withdrawal. Iran agreed. The United States and Britain took the issue to the United Nations (UN), and this, with the oil concessions, convinced the Soviets to withdraw troops in May 1946. The

COLD WAR IN THE MIDDLE EAST, 1945 – 1990

communist governments collapsed, and Iran cancelled the concessions and curtailed Tudeh influence.

This episode was a prelude to many confrontations between the Cold War powers in the Middle East. Iran continued as a front in the Cold War for many years, including the Central Intelligence Agency's successful efforts in 1953 to overthrow the Mossadeq government in Iran because of supposed Soviet influence. Iran then became a member of the Baghdad Pact, one of the links in worldwide alliances opposing the Soviet Union. Iran continued to be an ally of the United States until the overthrow of the shah in 1979, toward the end of the Cold War. After that Iran under Ayatollah Khomeini was almost equally opposed to both the United States and the USSR, one being named the "Great Satan" and the other the "Little Satan."

After Iran, the next Cold War arena in the Middle East was British Palestine. After World War II, Britain reduced its presence and costs outside Europe. France would do the same but more reluctantly. The Arab Middle East smelled the possibility of independence from the European empires. The United States and the Soviet Union were viewing the area as a future arena of competition.

In tandem with the British removal of forces, Israel's Labor Zionist government under David Ben-Gurion declared independence on May 14, 1948. The United States recognized the new state the same day as the Soviet Union, on May 18. A series of battles between Israel and invading Arab forces resulted in an Israeli victory and a cease-fire in early 1949, with Israeli admission to the UN in May 1949. At this time, Israel enjoyed support from both the United States and the Soviet Union.

The two superpowers had varying motivations; the United States realized that a strong presence in the Middle East would be crucial as the West European powers began to withdraw in order to secure vital petroleum resources and prevent the Soviet Union from exercising strong influence. Both sides provided substantial aid to Israel. Israel continued to be a focal point during the Cold War, but over time the United States prevailed.

The Cold War continued to shape the Middle East from the 1950s until the fall of the Soviet

➤ EGYPT AND THE ASWAN DAM CONTROVERSY

After World War II Great Britain decided to reduce its presence in the Middle East, hoping to be replaced by the United States or regional nations favorable to British interests. Egypt was nominally independent since 1922 and ruled by descendants of Muhammad Ali, the Albanian Ottoman pasha of Egypt after 1805. Britain left most of Egypt to King Faruk after the end of World War I, withdrawing its forces to the Suez Canal. The coup of 1952 overthrew the monarchy, and Gamal Abdel Nasser took control.

Britain and the United States recognized the new government, but the Soviet Union took little interest as Nasser continued to outlaw the Egyptian communist party. Nasser courted both sides for possible aid, using a position of nonalignment in the Cold War as a bargaining chip, hoping to become the leader of a resurgent Arab Middle East. The United States sought Nasser's support by promising funding for the Aswan Dam, which would control flooding of the Nile and provide vast amounts of hydroelectric energy. This would come with substantial military aid. The Soviets waited patiently on the sidelines to determine if Nasser's neutrality would be maintained with U.S. aid.

Secretary of State John Foster Dulles, however, took exception to Nasser's neutrality position and demanded allegiance before the United States would provide funds. At the same time the Soviets offered funding for the dam and military support. In 1955 Nasser concluded a military arms deal with Czechoslovakia and also accepted U.S. conditions for financing the Aswan Dam. The Cold War was at its height, and Dulles, having insisted on an all-or-nothing deal with Egypt, withdrew the U.S. offer on July 19, 1956. Nasser played his cards within a week by declaring that Egypt would nationalize the Suez Canal, accept Soviet funding for the Aswan Dam, and turn to the Warsaw Pact for future arms. Within months the balance of Cold War influence in Egypt had dramatically reversed.

—Dan Spector

Union. The competition ranged from North Africa in the west through Afghanistan in the east. As Morocco asserted its independence from the West in the late 1950s, it played both sides against each other. In 1959, Morocco obtained a U.S. agreement to return control of air force bases

to Moroccan control while also persuading the Soviets to provide military assistance. This did not result in a long-term commitment of this nation to the Soviets, and the United States later regained influence. In the mid-1980s Algeria obtained Soviet military aid in the form of air defense missiles. This too did not result in a sustained shift toward the Soviet Bloc.

Both superpowers vied for influence in Afghanistan after World War II, with the Soviets gaining ground during the reign of a liberal member of the royal family, Mohammed Daoud Khan, as prime minister from 1953 to 1963. This included a loan of \$3.5 million in 1954, countered by smaller amounts of aid from the United States during the 1950s. A royal power struggle left Daoud outside government in 1963, but he returned after a coup in 1973. Although he leaned toward the Soviets, Daoud refused to be a puppet and did not bow to demands for more communist participation in government. This along with opposition from traditional Muslims opposed to a move toward secular government led to a coup during April 27–28, 1978, in which Daoud lost his life and the monarchy was abolished. Unwilling to leave events in Afghanistan to chance, the Soviet Union sent troops across the border on December 27, 1979, and installed a government favorable to them under Babrak Karmal. Soon after, Soviet troops spent nearly a decade unsuccessfully battling anticommunist insurgents.

Egypt was the focus of a Cold War struggle that began with the end of British control in the early 1950s. As elsewhere, local leaders played both sides for their national and regional goals. Key players were Gamal Abdel Nasser and Anwar Sadat, both of whom courted both sides, changing allegiances or professing neutrality as opportunities arose. The construction of the Aswan Dam on the Nile provides an insight into how intense and complex the Cold War was.

After the Cold War the Middle East faced an entirely different set of circumstances. The United States and its allies were the most powerful force in the area, but regional conflicts took on a greater importance to the peoples of the Middle East.

—Daniel Spector

Cold War in South Asia

At the dawn of the Cold War, the role of newly independent postcolonial South Asia was not defined. Although both Pakistan and India had dense populations and vast and diverse territories, neither was viewed as having the strategic importance of Western Europe or Japan. The subcontinent was not as industrialized, did not have any particularly valuable natural resources, and did not command strategic military assets. Thus, the U.S. and Soviet initial responses to these nonthreatening nation-states bordered on indifference.

On the American side, this changed following the outbreak of the Korean War. Now that the Cold War had metamorphosed into a hot war in Asia, strategists in President Harry S. Truman's administration insisted upon South Asia's importance to American Cold War objectives. However, there were divergent views over whether it would be best to align with India or Pakistan. The consequence of a successful pursuit of India would be the claim of being associated with the developing world's most prominent—and democratic—nonaligned state. However, other advisers pointed to Pakistan's strategic proximity to both the Soviet Union and the Middle East.

For India, the nearly half-century of relations that followed between itself and the superpowers was inconsistent. India tended to align itself more closely with the Soviets or the United States depending on India's perceived security interests, which centered on its often hostile relations with its northern neighbor, Pakistan. India would eventually fight three wars with Pakistan by 2000. Another benefit of at times accommodating the Soviet Union was that India gained support against China, with which it had several violent clashes over borders and strained relations following the Chinese occupation of Tibet. Confronted with these challenges that were not products of the Cold War, India under Jawaharlal Nehru preferred to remain nonaligned in the superpower conflict. This refusal to endorse the U.S. perception of the Soviet threat angered

American policy makers, yet later, under Indira Gandhi, India went even further by establishing even closer security and political ties with Moscow.

While Indian agreements with the Soviet Union disturbed American foreign policy planners, India meanwhile resented being accorded low priority in American foreign policy. India had one-sixth of the Earth's population and was strategically placed adjacent to oil supply routes and near another great power, China, all of which indicated India's Cold War importance. However, Americans did not appreciate criticism of its handling of the Vietnam War or Indian assumptions that every aspect of U.S. foreign policy contained ulterior motives. On both sides, the breakdown in trust was a product of the era. After two world wars in little more than a generation, it was hardly irrational to fear a third, and with the proliferation of nuclear weapons, some people believed that the next war would be the last.

Pakistan, after obtaining independence in 1947, faced the struggles of an impoverished nation with an unclear future and believed that superpowers such as the United States would more likely prefer closer ties with its much larger southern neighbor, India. Yet after New Delhi chose a neutralist path, Pakistan became more attractive in the mid-1950s as a potential partner in American security arrangements designed to contain potential Soviet expansion in the Middle East. Since then, when Pakistan became viewed as important to American security interests—such as during President Richard Nixon's overtures to China or during the Soviet invasion of Afghanistan in the 1980s—relations were closer, but at other times, such as during the presidencies of John Kennedy, Lyndon Johnson, and Jimmy Carter, relations were much more tense.

Pakistani leaders regarded such U.S. oscillation as vacillation, and Americans considered Pakistan overly consumed with India. The reason for so many mixed signals in U.S.-Pakistani relations was that their respective security interests—when aligned, the key factor in close relations—were often out of harmony. Absent a more significant basis for ties, differences and disputes were inevitable.

The primary security concern of Pakistan was disagreement with India, especially over Kashmir.

➤ CHRONOLOGY OF THE COLD WAR IN SOUTH ASIA

- 1947—End of British rule in South Asia.
- 1947—Partition of region into Hindu India and Muslim Pakistan.
- 1948—First Indo-Pakistani War over Kashmir.
- 1948—Gandhi assassinated by Hindu extremist.
- 1948—Muhammed Ali Jinnah, first president of Pakistan, dies.
- 1951—Indian prime minister Nehru comes to power.
- 1951—Jinnah's successor Liaquat Ali Khan is assassinated.
- 1956—Pakistani constitution written, declaring Pakistan an Islamic republic.
- 1962—India loses war with China over border disputes.
- 1964—Death of Indian prime minister Nehru.
- 1965—Second Indo-Pakistani War over Kashmir.
- 1966—Nehru's daughter Indira Gandhi becomes prime minister of India.

—Luke Nichter

This meant that Pakistan endured heavier military and security expenditures than a newly independent country with an underdeveloped economy could maintain. When Pakistan realized that it was unable to match, dollar for dollar, military expenditures with India, it sought parity with its southern neighbor by other diplomatic conventions, such as cozying up to China in the 1960s, going to war with India over Kashmir in 1965, and implementing a nuclear weapons program in the mid-1970s.

On the American side, although U.S. policy makers had their share of difficulties with India, the country was never considered hostile or a threat to Americans. The United States generally tried to stay out of the deep-seated dispute between Pakistan and India. The major exception was during the Nixon administration. Because Pakistan had reached out to China in the 1960s, the Nixon administration found Pakistan's ties to the reclusive and secretive People's Republic of China valuable in the process of beginning Sino-American rapprochement.

Overall, from the late 1940s until the Iron Curtain disintegrated in 1989, the evolution in relations between the superpowers and India and Pakistan and the status of South Asia itself remained in the shadow of the Cold War struggle between the United States and what Reagan called the "evil empire." The United States expected both India and Pakistan to be cooperative allies, but when one of the junior partners refused to play the game according to Washington's rules, trouble ensued. Furthermore, debates and diplomacy that centered on which nations should or should not be allowed nuclear weapons also developed into a major source of friction beginning in the mid-1970s.

It is likely that the superpowers overplayed the importance of South Asia in the Cold War. U.S. policy makers' one-time notion that Pakistan could mobilize sufficient forces to help deter Soviet military marauding in the Middle East was not realistic. In fact, on balance South Asia contributed little to Western defense efforts in the Middle East—the alliance's basic purpose—and added almost nothing to the overall global strength of the United States, not militarily, not politically, and certainly not economically.

As the dissolution of the Soviet Union became inevitable in the late 1980s, the status of India and Pakistan once again became unclear. Although the two principal sources of past friction—American arms sales to Pakistan and India's close ties with the Soviet Union—had been lessened or removed, the United States failed to translate its overwhelming military power over the previous four decades into lasting influence.

The superpowers deliberately extended the Cold War into South Asia and sought to align both Pakistan and India with their respective blocs, principally because of exaggerated American concerns about its own vulnerability and communism's presumed military and ideological threat. Policy makers in both the Soviet Union and the United States habitually evaluated India and Pakistan—as well as states in other less-developed regions—with a Cold War viewpoint. Such evaluations, more often than not, proved inaccurate.

The Cold War in East Asia

The confrontation between the West and the Communist Bloc after 1947 as well as the growth of the Sino-Soviet rivalry from the late 1960s onward was an important feature of the East Asian political landscape in the Cold War era. Misunderstanding and miscalculation by the United States, the Soviet Union, and the People's Republic of China (PRC) exacerbated regional crises and military aggrandizement, and yet their rationality and mutual interests helped avoid nuclear war and prevented the spillover of regional war in the world. U.S. protégés such as

COLD WAR IN FAR EAST, 1945 – 1990

➤ U.S. MILITARY BASES IN THE PHILIPPINES

The presence of U.S. military bases in the Philippines has its roots in the American victory against Spain in 1898. Despite Filipino resistance against U.S. occupation, the United States made the Philippines its military stronghold in Asia by establishing Manila as the region's largest naval station, to which later was added Clark Air Base on Luzon Island. On December 8, 1941, after Japan's attack on Pearl Harbor occurred, Japanese air assaults also heavily damaged the Clark Air Base. A series of fierce battles between the U.S.-Filipino army and Japan eventually forced the U.S. troops to retreat from the Philippines in 1942. In October 1944 General Douglas MacArthur's Allied forces returned and landed on Leyte Island. Despite the independence of the Philippines in 1946, the U.S. military presence remained throughout the Cold War era. The 1951 Mutual Defense Pact between the Philippines and the United States was an important component of the U.S. military strategy of containing communism in Asia. Clark Air Base, together with the string of U.S. bases in Japan, served as the backbone of logistical support for U.S. troops during the Vietnam War. In 1992 U.S. troops were withdrawn from the Philippines; however, mutual defense treaties have remained in effect. Most recently, American advisers joined Philippine forces in maneuvers against Abu Sayyaf ("bearer of the sword") and other terrorist groups linked to al-Qaeda in the southern area of the island archipelago.

—*Ryoko Nakano*

Japan, South Korea, and Taiwan enjoyed unprecedented economic development during the Cold War, while China, after its rapprochement with noncommunist countries in the 1970s, made diplomatic and economic overtures to the world. The Chinese communist capture of Mainland China in 1949 fostered the U.S. perception that communism was on the march in East Asia. The newly formed PRC as well as the Soviet Union encouraged Kim Il Sung's invasion of South Korean territory in June 1950. U.S.-led United Nations (UN) forces intervened in the war and penetrated the North beyond the original demarcation border along the 38th parallel. The presence of U.S. troops near Manchuria triggered

China's entry into the war. Military supplies and air cover provided for Chinese troops by the Soviet Union prolonged the war, which was finally ended in 1953 by freezing the original partition of the Korean peninsula.

The Korean War provided important lessons to both the United States and the Soviet Union, both of which originally had been reluctant to abrogate their obligations under the Yalta agreement. In order to prepare for a potential conflict with the communist regime, the United States made a decisive turn by dispatching troops to alliance partners such as Japan, South Korea, and the Philippines. Both of the superpowers refrained from direct confrontation in order to contain the risk of nuclear war. The Korean War also gave China an incentive to strengthen its military power, which intensified arms competition in East Asia.

At the peak of the Korean War, Japan gained *de jure* independence by signing the San Francisco Peace Treaty on September 8, 1951, while also signing the U.S.-Japan Security Treaty. These treaties marked the end of World War II in East Asia, terminated Japan's position as an imperial power, and, among other points, redistributed its overseas possessions, formalized Japan's acceptance of judgments by War Crimes Tribunals and its renunciation of future military aggression, and placed Okinawa under U.S. authority. The Soviet Union did not sign the peace treaty due to the Soviet-Japan territorial disputes over Sakhalin and the Kurile Islands. Under the U.S.-Japan security pact, the United States was obliged to defend Japan, while Japan did not have a reciprocal obligation due to the renunciation of war clause (Article 9) in the Japanese Constitution. Japan instead provided the United States with strategically important bases and developed its self-defense forces within the framework of U.S.-Japan security agreements for enabling peace and security in the Far East.

The United States aimed at shaping the East Asian region outside the U.S.-Soviet-Chinese triangle. Taiwan, ruled under Jiang Jieshi's (Chiang Kai-shek's) Nationalist government, was given military and economic support from the United States. The Taiwan Straits Crisis in 1954–1958 was the most critical time of the U.S.-China confrontation over Taiwan. In response to Jiang's

demands, U.S. president Dwight D. Eisenhower sent the Seventh Fleet to the Taiwan Strait to defend Taiwan's Quemoy and Matsu islands from communist China and enacted the Taiwan Resolution in 1955 committing the United States to defend Taiwan.

Deteriorating relations between the Soviet Union and China had reached a crisis point by 1969. A series of events made it clear that the two communist countries would go in different directions: Khrushchev's speech criticizing Stalin in 1956 without any prior consultation with China, Soviet refusal to transfer its nuclear technology to China in 1959, Chairman Mao Zedong's political elimination of so-called Soviet advisers in the period of the Great Leap Forward (1958–1962), China's assertive policy against India, and the two border clashes between the Soviets and the Chinese in 1969. This Sino-Soviet split caused a fundamental transformation of the political climate, undermining perceptions of communism as a monolithic bloc, and eventually led to the Sino-U.S. détente. Mao Zedong aimed at developing Sino-U.S. cooperation to counter the Soviet Union. U.S. president Richard M. Nixon and Secretary of State Henry Kissinger had the same interest in regard to the Soviet Union and wanted to make an honorable retreat from the Vietnam War by gaining Chinese support.

Nixon's secret negotiations with China came as a great surprise and even appeared as a betrayal to Japan, which had no alternative but to accept U.S. policy preferences. Nevertheless, Prime Minister Tanaka Kakuei swiftly normalized relations with China in 1972. After China and Japan signed the Treaty of Peace and Friendship in 1978, with an antihegemony clause implying that the Soviet Union constituted a threat to both, they developed friendly relationships until 1989 while setting aside divisive issues such as the Taiwan problem, territorial rights of the Diaoyu Islands (called Senkaku by the Japanese), and problems of the alleged bias within the Japanese educational system in interpreting the history of Japan's imperialist past. The United States also reached a compromise with China by withdrawing U.S. troops from Taiwan, which lost its UN seat in 1971. U.S. détente with China transformed the regional landscape dramatically.

By the end of the Cold War, the United States had become an unprecedented hegemonic power in East Asia. Together with alliance partners, the United States consolidated its strategic role as the guarantor of East Asian security. Owing substantially to U.S. commercial involvement in this region, Japan, South Korea, and Taiwan headed along the path of democracy and economic prosperity. Hong Kong, leased by China to Britain until 1997, served as a reliable means of access for the Chinese to the capital and technology of the Western market.

The bilateral approach that dominated East Asian politics sidestepped the painstaking negotiations necessary to establish a multilateral framework capable of solving regional tensions. Despite Deng Xiaoping's compromising proposal of the one country, two systems policy for inter-Chinese relations, the Taiwan problem continued to be explosive. In addition, military tensions on the Korean peninsula never ended due to the fear that the North Korean regime would gain possession of nuclear arms. Even though the disintegration of the Soviet Union decreased the risk of nuclear war in East Asia, the ghosts of Cold War uncertainty and instability still haunted the region at the opening of the twenty-first century.

Cold War in Latin America

The Cold War originated as a political, economic, and ideological competition between the United

THE CUBAN MISSILE CRISIS (1962)

View from a U.S. reconnaissance aircraft of Mariel Bay, Cuba, showing Soviet missile equipment and transport ships in 1962. (Library of Congress)

In October 1962, the world came to the brink of nuclear war. What came to be known as the Cuban Missile Crisis demonstrated the great danger of Cold War competition and the delicate balance negotiated between nuclear superpowers caught up in an arms race. In alliance with revolutionary Cuba, Russian premier Nikita Khrushchev supervised the secret construction of missile bases on the island. When U.S. intelligence informed President John F. Kennedy of the threat of nuclear weapons 90 miles from Florida, a tense showdown between the two heads of state occurred, lasting 13 long days while the world held its breath. Kennedy demanded the immediate removal of all weapons from the island and set up a naval blockade off the Cuban coast, preventing Soviet ships from delivering additional missiles and construction materials. Khrushchev finally conceded to Kennedy's demands, and the Soviet Union removed all installations and weapons from the island. In exchange, the United States agreed to withdraw medium-range missiles from Turkey and not to intervene in Cuba.

States and the Soviet Union in the aftermath of World War II. It became a global conflict between a communist Eastern Bloc and the capitalist U.S.-led West and ended with the Soviet Union's collapse in the 1990s. In this period, Latin America became an important contested arena between the Soviet Union and the United States.

Between the late 1940s and the early 1990s Cold War ideologies shaped all political and economic interaction between Latin America and the United States. New U.S. foreign policy approaches produced novel forms of foreign intervention. On the global level, U.S. foreign policy shifted between containment, aimed at preventing the spread of communism, and the policy of détente, aimed at securing a balance of power and thereby peaceful coexistence with the Soviet Union. The domino theory complemented these doctrines, implying that if one country came under communist influence, others near it would fall in a domino effect. As a result, the United States supported some authoritarian leaders as a lesser evil, backing anticommunist dictators such as Fulgencio Batista in Cuba (1952–1959), the Somoza dynasty in Nicaragua (1936–1979), and Augusto Pinochet in Chile (1973–1989). The United States also began to train Latin American militaries in 1946, when the School of the Americas opened in Panama as a military academy for the hemisphere. Its doctrine of national security taught that the principal threat to a nation was subversion within its own boundaries and became the guiding principle behind dictatorships in Argentina, Brazil, Chile, Uruguay, and several Central American countries.

Cold War tensions inspired a number of treaties and support programs between the United States and Latin America. In 1947 delegates from the United States and 19 Latin American countries signed the Inter-American Treaty of Reciprocal Assistance, or Rio Pact, to strengthen cooperation against threats to the hemisphere. In 1948 American leaders established the Organization of American States (OAS) in the spirit of further regional unity. When Vice President Richard Nixon encountered strong anti-American sentiment on his goodwill tour of Latin America in 1958, it became clear that the United States had become unpopular and that alliances needed

to go further to secure the support of Latin American citizens against communism. The 1959 Cuban Revolution emphasized the need for increased intervention. In 1961 President John F. Kennedy helped establish the Alliance for Progress, a new foreign policy approach aimed at promoting development through an increase of loans and cooperation.

Throughout the 1960s, Kennedy's Alliance for Progress aimed at bringing reform and development to Latin American nations. The charter called for an increase in per capita income, more equitable distribution of land and wealth, and, most importantly, economic and social planning as the basis for democratic government and a free market economy. The plan intended that aid programs would bring the benefits of capitalism to the poor and weaken support for communism. Yet economic support dropped sharply under President Nixon in the late 1960s. Despite some improvements in land reforms, education, and health care services, Latin American elites resisted the changes, the redistribution was limited, and, in the words of Chilean President Eduardo Frei, "the Alliance . . . lost its way."

Covert military operations by the U.S. Central Intelligence Agency (CIA) became important extensions of U.S. foreign policy and the fight against communism. Justified through fears of communist takeovers, U.S.-supported armed interventions took place in nations including Guatemala (1954), Cuba (1961), the Dominican Republic (1965), Chile (1973), Nicaragua (1979), and Grenada (1983). The 1954 overthrow of Jacobo Arbenz's constitutional government in Guatemala exemplifies the nature and consequences of Cold War interventions driven by ideology. Arbenz had introduced land reforms and, in the process, seized unused territory owned by the U.S. United Fruit Company with the promise of compensation. CIA forces soon helped expose the president's goal to create a communist state. With U.S. backing, Arbenz was replaced by Carlos Castillo Armas, a dictator who dismantled previous land reforms, outlawed political parties, threatened striking workers with the death penalty, and violently curbed unrest. In the course of the next three decades in Guatemala, more than 200,000 citizens lost their lives.

In Latin America some political leaders and citizens deeply resented U.S. interventions as manifestations of imperialism and as threats to their sovereignty. Resistance to Cold War interference reached from small-scale protests to outright revolution. Argentine physician Ernesto "Che" Guevara played an influential role in this resistance by the late 1950s, as he became one of the leaders in the 1959 Cuban Revolution. In 1954 Guevara witnessed the deposition of President Arbenz in Guatemala and began to defend the need for revolution on his path to social justice. In Mexico, Guevara met Cuban exile and like-minded revolutionary Fidel Castro. The two returned to Cuba with a group of supporters and initiated a new chapter in the history of Latin America in the Cold War era. (Guevara later became an icon of Latin American resistance when the CIA killed him in Bolivia in 1967. A larger-than-life romanticized image of his role as a revolutionary has lived on after his violent death.)

In 1959 the 26th of July movement, led by Castro and Guevara, entered Havana after six years of guerrilla warfare and deposed U.S.-supported dictator Fulgencio Batista. Breaking all economic ties with the United States, the new leadership made the Soviet Union Cuba's major trading partner. President Dwight D. Eisenhower's administration broke diplomatic relations with Cuba, and tensions increased when Castro declared communism the official doctrine of revolutionary Cuban development. In response, the United States organized a force of anti-Castro exiles to embark on an invasion of the Cuban Bay of Pigs in 1961. This intervention not only became the biggest failure of covert actions against Cuba and other Latin American nations but also strengthened Castro's position as head of state of the last surviving communist nation in the hemisphere. A more dangerous Cold War emergency followed the Bay of Pigs invasion: in 1962, the Cuban Missile Crisis brought the world dramatically close to nuclear war.

Other Latin American leaders promoted less drastic programs of revolutionary change but were perceived as equally threatening to the United States. In 1970 socialist president Salvador Allende won democratic elections in Chile. His coalition government promoted a path of peaceful revolution, generating social justice and

economic redistribution within the margins of the democratic constitution. Although Allende overtly rejected affiliation with communism, the CIA provided substantial financial support to his opposition. In light of the Cold War fears of leftist political leaders, the United States supported a military coup that killed Allende and brought to power General Augusto Pinochet on September 11, 1973. In the course of the Pinochet dictatorship (1973–1989) potential opponents were arrested and tortured and often disappeared. Yet this was acceptable in the Cold War context so long as economic policies conformed to the standards of neoliberal capitalism, and the regime ended all previous programs of redistribution.

Bilateral relations between the United States and Latin American nations transformed significantly with the end of Cold War tensions. Anti-communist crusades were no longer important to the maintenance of global balance, and new global policy concerns have replaced the bipolar worldview limited to East-West competitions of previous decades. Cuba and the endurance of its revolutionary position against unremitting U.S. aggression remained one of the few leftovers of an era.

The Korean War, 1950–1953

The Korean War was the first major hot war of the Cold War and was fought on the Korean Pen-

insula between the Soviet and Chinese-backed communist North Korea and the U.S.-sponsored noncommunist South Korea from 1950 to 1953. The conflict began in June 1950 when North Korea invaded South Korea. The situation quickly escalated, with United Nations (UN) forces under American leadership entering the war in support of the southern portion of the country. Chinese forces with logistical Soviet support eventually entered the war in support of North Korean communist forces.

Korea had been divided at the end of World War II at the 38th parallel under an agreement by the Soviet Union and the United States upon the surrender of occupying Japanese forces. Both sides acknowledged that they could organize the political structure of their respective zones of occupation as they wished. UN efforts to reunify the country came to nothing, as the northern section refused to allow free elections on its soil. In 1948, the UN elections commission held elections in the southern half of Korea (Republic of Korea, ROK), leading to the election of Syngman Rhee as president. North Korea reciprocated by establishing itself as the Democratic People's Republic of Korea (DPRK) under the leadership of Prime Minister Kim Il Sung with full Soviet and Chinese Communist Party (CCP) support. The establishment of the People's Republic of China (PRC) in 1949 by the CCP cemented its support of the communist North Korean state.

By 1949, the United States had withdrawn its remaining postwar garrison forces from South Korea, leaving a small group of advisers for the training of the ROK military. In 1950, U.S. secretary of state Dean Acheson declared that the American strategic defense perimeter did not include Korea, leading some in the communist world to believe that this was a blank check for North Korea to acquire South Korea. After receiving the blessings of both Soviet general secretary Josef Stalin and Chinese chairman Mao Zedong, Kim Il Sung launched a surprise invasion of South Korea on June 25, 1950. This aggression was the official beginning of the Korean War. Immediately, U.S. president Harry Truman committed small air and naval contingents to South Korea and ensured the passing of a UN resolution condemning the invasion. The Soviets abstained from the Security Council voting in the

➤ KOREAN DEMILITARIZED ZONE (DMZ)

The Korean Demilitarized Zone (DMZ), established by the 1953 armistice that ended the Korean War, is a strip of land running across the Korean Peninsula that serves as a buffer zone separating North and South Korea. The DMZ cuts the Korean Peninsula geographically, approximately in half, across the old 38th parallel that divided Korea before the conflict. At a length of 155 miles (248 kilometers) and a width of 2.5 miles (4 kilometers), it is currently the most heavily armed border in the world.

The Joint Security Area (JSA), or Panmunjom, is the only section of the DMZ where South and North Korean forces stand facing each other. The section is reserved between the two Koreas for diplomatic efforts. Most of the DMZ is largely bereft of humans and military equipment, which are restricted on both sides to 100 miles (160 kilometers) away from the armistice line of demarcation. However, along these parameters it is heavily fortified with pillboxes, watchtowers, and other defensive installations along with both South Korean and U.S. troops facing North Korean troops, albeit at a long distance.

—Abraham O. Mendoza

hopes that this would be assumed to be a veto. The vote was followed by a UN resolution in July authorizing a UN multinational force under U.S. leadership. This UN force was composed mostly of U.S. and ROK troops but also had sizable contingents from Britain, Australia, Canada, Turkey, and New Zealand. The Korean conflict quickened the formation of the North Atlantic Treaty Organization (NATO), the reincorporation of West Germany into the Western fold, and the widespread stationing of American troops in Europe.

The North Korean military continued to press forward into South Korea, scattering U.S. and ROK troops. By August, the beleaguered U.S. forces had established the Pusan perimeter at the southernmost region of the Korean Peninsula. However, by August, General Douglas MacArthur's surprise landing and victory at Inchon defeated the ROK's armies, putting the UN forces on the offensive. Two months later, Truman decided that in order to prevent the intervention of the Soviets or the Chinese (the newly formed PRC), U.S. forces would remain to the south of the 38th parallel. However, they would continue to allow ROK forces to conduct limited operations in North Korea with the condition of acting as support if either the Soviets or the Chinese intervened.

ROK forces retreated into North Korea but did not officially surrender. DPRK forces entered North Korea in early October and met little resistance, followed by U.S. requests to the UN General Assembly for a resolution to continue the struggle. This resolution provided a UN plan to seek the reunification of Korea, leading U.S. forces to enter Korea on October 7 in spite of a major Chinese buildup on the border with North Korea. Chinese forces began to deploy into North Korea, snatching potential victory from joint UN forces. Truman was reluctant to escalate hostilities, coming into direct conflict with MacArthur, who advocated attacking targets in Manchuria to hinder the deployment of Chinese troops and going as far as suggesting the use of atomic weapons. These differences over military strategy led to Truman's firing of MacArthur in April 1951.

From November 1950 to 1951, successful Chinese offensives had drastically altered the conflict. UN forces eventually halted the Chinese

advance and launched a major offensive, restoring a line of defense just north of the 38th parallel, turning the conflict into a bloody and costly stalemate by May 1951. At this point, Truman was willing to settle for a diplomatic solution with the North Koreans, the Soviets, and the Chinese, all advocating a return to the territorial status quo that preceded the conflict. However, negotiations stalled as disagreements over cease-fire agreements, prisoner exchanges, and the withdrawal of military forces complicated deliberations. Meanwhile, as both sides continued limited military engagements, casualties continued to mount. Casualties for military personnel were an estimated 400,000 for the Chinese, 54,246 for the United States, 215,000 for North Korea, and 47,000 for South Korea. An estimated 2 million Korean civilians were also killed during the war, approximately 1 million for either side, as a result of artillery attacks, aerial bombardments, and other direct military engagements resulting in collateral damage.

The Korean Armistice Agreement, signed on July 27, 1953, finally ended the bloody conflict. The South Korean government's fears of a Chinese garrison allied with North Korean forces menacing its existence just across the border were allayed by Eisenhower's promises of substantial U.S. aid and a security pact for the ROK. However, the armistice that ended hostilities divided Korea politically and geographically and never fostered a decisive treaty ending the war. The Korean War also established that while Cold War antagonisms in such limited engagement proxy wars did not lead to direct military engagement by the major world powers (Chinese troops were considered volunteers and not officially armed combatants of the PRC), it did complicate matters of foreign policy in other world regions, particularly issues related to the division of Germany.

South Vietnam and the Cold War

South Vietnam (1954–1975) is the common term for the political entity south of the 17th parallel of present-day Vietnam. Its creation was an indirect result of the 1954 Geneva Conference. As part of the larger Cold War pattern of conflicts and compromises, the conference dealt first with the end of the Korean War and then turned its attention to settling the conflict between France and communist-led Vietnamese guerrilla forces, known as the First Indochina War. Besides Laos and Cambodia, the participants for the Indochinese portion fell squarely into anticommunist and communist sides. On one side were France, Britain, the United States, and the pro-Western

Republic of Vietnam president Ngo Dinh Diem (1955–1963) casts a ballot in Saigon. Diem resisted democratization of South Vietnam and his dictatorial, often brutal, rule led to withdrawal of U.S. support, a coup d'état, and his assassination in 1963. (Library of Congress)

State of Vietnam, which was led by the former emperor Bao Dai. On the other side were the Soviet Union, China, and the Democratic Republic of Vietnam (DRV), which had just decisively won the Battle of Dien Bien Phu against France. Signed by only France and the DRV, the Geneva Accords agreed to a temporary partition of Vietnam—the north to be controlled by the DRV and the south by the State of Vietnam—to be followed by a general election two years later.

At the start of the partition, South Vietnam had a new premier in Ngo Dinh Diem. The next year, the U.S.-backed Diem successfully deposed Bao Dai in a referendum and created the new Republic of Vietnam (RVN), with its capital in Saigon. Diem also declared that because his government had not signed the Geneva Accords, it was not bound to honor the mandate for a general election. South Vietnam quickly became a major Cold War battleground as the United States pumped in massive aid to help Diem build a viable nation and contain the spread of communism in Southeast Asia. Not having the chance to win a political victory, North Vietnam sought economic and military aid from China and the Soviet Union to build socialism in the north while aiding an anti-Diem insurgency in the south. Both governments refused to recognize each other and instead claimed authority over the entire country. It took two more decades, continuous warfare, and millions of dead and wounded combatants and civilians before Vietnam became one again.

The political history of South Vietnam can be divided into three periods. The first and longest was under Diem (July 1954 to November 1963). The first half of this period saw three major developments: the immigration of nearly 1 million anticommunist northerners, including many Catholics; Diem's antidissident campaign that suppressed underground communists but also alienated many noncommunist Vietnamese; and, with American help, the training of South Vietnamese administrative and military personnel. The second half of the period saw renewed insurgency in the countryside, an increase from 700 to 16,000 American advisers, growing conflicts between Diem and U.S. president John F. Kennedy's administration over nation building and anti-insurgent strategy, and intensifying urban

➤ SOUTH VIETNAMESE URBAN CULTURE

Although most Vietnamese lived in the countryside and engaged in agriculture, the two decades of South Vietnam's existence marked an important shift toward urbanization. The Americanization of the war played a major role in the shift. Bombing and warfare in the countryside created a refugee crisis and drove many people toward the cities. In addition, the massive presence of American personnel in urban areas led to the growth of a service sector and an explosion in the black market. In Western media, Saigon and other Vietnamese cities were often portrayed as full of bars, prostitutes, drug pushers, and beggars.

However, the American presence alone did not account for the growing significance of the urban society, and wartime and postwar portrayals did not show more than what met the eye. Since at least the 1920s, Vietnamese society underwent a profound shift in morals, manners, and modes of thinking. While nationalism occupied a central place in the collective psyche, there was also a rise in cultural acceptance and encouragement of a more acquisitive individualism. This rise was most obvious in South Vietnamese urban society, which encouraged the growth of the bourgeoisie as well as bourgeois values. Widely lauded in the popular culture were virtues such as determination, patience, hard work, and development of God-given talents. In particular, poets and fiction writers were held in high regard for their creative abilities. But singers and songwriters of popular music were also celebrated for expressing more private sentiments that were shared by their audience.

The abundance of opportunities for print and recording helped create a new phenomenon in modern Vietnamese culture: the rise of women as popular writers and singers. Among the most consequential women novelists were the best-selling Madame Tung Long and the prize-winning Nha Ca, and among the most beloved female singers were the northern-voiced Khanh Ly and the southern-voiced Phuong Dung. Whether they were creators or reflectors of increasingly individualized sentiments is a question open to debate. But their popularity pointed to the deeper shift toward a more acquisitive and individualistic sensibility of a postcolonial society.

—Tuan Hoang

discontent in regard to Diem and his style of family rule. Buddhist protests ignited in the summer of 1963; a military coup followed in the fall, and its leaders killed Diem and his brother-adviser Nhu.

Following Diem's death was an interregnum period (November 1963 to September 1967) characterized by a series of military or military-backed governments that were typically accompanied by coups and countercoups. In the first half of this period, the most prominent figure was General Nguyen Khanh, who had the support of U.S. president Lyndon B. Johnson's government but was subsequently ousted by his fellow military leaders in February 1965. The second half saw a War Cabinet government led by head of state Nguyen Van Thieu and Premier Nguyen Cao Ky. This period witnessed the start of U.S.-led bombing of North Vietnam in retaliation for increasing communist attacks and the rapid introduction of U.S. combat troops that Americanized the war. The last period, the Second Republic (September 1967 to April 1975), saw its first presidential election in 1967 and the second in 1971, both of which were won by Thieu.

Various Saigon governments, controlling the cities but only parts of the South Vietnamese countryside, were not the only ones to claim political legitimacy throughout these periods. Having gained revolutionary support from many rural people during the First Indochina War, the communists in South Vietnam suffered high losses during Diem's antidissident campaign but nevertheless survived. Called the Vietcong by South Vietnamese and Americans, they received substantial backing from North Vietnam and formed the National Liberation Front (NLF) in 1960 to challenge Diem and the subsequent U.S.-supported governments. Following Diem's death, political instability in Saigon and the weak performance of the South Vietnamese military emboldened the Vietcong to increase their attacks, leading to the Americanization of the war in the summer of 1965. North Vietnam itself had already decided at the end of 1963 to expand infiltration of supplies and personnel into the south via the Ho Chi Minh Trail that went through Laos and Cambodia. The war thus escalated swiftly and culminated in the Tet Offensive

during the lunar New Year's holidays of 1968, when NLF and North Vietnamese forces carried out a massive and well-coordinated assault on urban areas, including Saigon. Although the NLF suffered tremendous losses, the offense's ferocity shook the American public's remaining support for the war.

Starting in 1969 the United States began to withdraw its troops, and warfare shifted increasingly from a guerrilla to a conventional struggle between the Saigon and Hanoi armies. In the spring of 1972, North Vietnamese forces made an incursion across the partition line but were eventually driven back by the South Vietnamese Army and American air support. The NLF ably maneuvered to be a participant in the Paris Peace Conference that also involved North Vietnam, South Vietnam, and the United States. The Paris Accords of 1973 ended all forms of American military involvement. Although the Thieu government was initially unwilling to sign the accords, it went along under American pressure. In the spring of 1975, Hanoi launched a second attack and forced the Saigon government to surrender on April 30. The next year, the two countries were formally reunified.

Afghan Wars

Not to be confused with the Anglo-Afghan Wars, the Afghan War or Soviet-Afghan War (1979–1989) refers to the brutal conflict fought between the Soviet Army and the Soviet Union's Afghan allies against the staunchly anticommunist Afghan mujahideen (holy warriors) in which So-

viet forces killed 1.3 million Afghans and forced another 5.5 million Afghans into exile.

The origins of the Afghan War lay in the turbulent domestic politics of late 1970s Afghanistan. During the Saur (April) Revolution of 1978, leftist military officers overthrew the government of Muhammad Daoud Khan on April 27, 1978. Following their seizure of power, the Khalq (meaning “the People”) and Parcham (meaning “Banner” or “Flag”) factions of the People’s Democratic Party of Afghanistan (Jamiyat-e Demokratati-e Khakq-e Afghanistan, PDPA) formed a new government and appointed Nour Mohammed Taraki, leader of the Khalq, as president of the Revolutionary Council and Hafizullah Amin, leader of the Parcham, as prime minister. Soon thereafter, Taraki set about changing Afghanistan from a feudal theocratic society to a socialist society as he embarked on a series of sweeping social reforms that ignored the traditional tribal elite and alienated large portions of the rural Afghanistan populace. Opposition to these reforms and to the changes to Afghan society led to clashes between mujahideen and Afghan security forces in the countryside. Soldiers, units, and entire brigades deserted to join the mujahideen. By early 1979 there was armed resistance in 25 of the 28 provinces of Afghanistan, and over half of the officer corps was either purged, executed, or had deserted. As the state began to fail, the Afghan army and civil bureaucracy disintegrated, and the Soviets resolved to come to the aid of their Afghan allies.

During this unrest, the PDPA’s Khalq and Parcham coalition proved temporary. Friction between these factions eventually led to a power struggle in which Parcham leader Amin launched a coup d’état on September 14, 1979, seizing the presidential palace and secretly executing Taraki. Amin then declared himself president of the People’s Republic of Afghanistan. Amin’s rule proved no better, as Afghanistan spun out of control and out of Moscow’s orbit.

Following years of internal political bickering between the Khalq and the Parcham factions, the assassination of Taraki provided the Soviet Union with the excuse to invade Afghanistan to save the Afghan communist revolution. On December 24, 1979, Soviet forces quickly seized Afghanistan’s capital, Kabul. Although Soviet

➤ U.S. INVOLVEMENT IN THE SOVIET-AFGHAN WAR

Compared to the Vietnam War by many historians, the Soviet-Afghan War (1979–1989) was fought by a major industrial power with modern conventional forces and military hardware, able to hold on to major urban areas but pitted against nonconventional guerrilla forces, sustained by the sympathetic countryside and by antagonistic international sponsors. Unlike Vietnam, this time it was the Soviet Union and not the United States in the role of invading superpower. U.S. support of the mujahideen then battling the Soviets through the supply of rocket-propelled grenades and stinger missiles, typically supplied by third parties such as the Pakistanis, ensured a long war of attrition for Soviet forces bogged down in the difficult terrain fighting against partisan guerrillas. Presidents Jimmy Carter and Ronald Reagan both viewed the Soviet-Afghan War as a critical theater for the global Cold War and ensured the supply of crucial materials for rebel Afghan forces and their mujahideen allies, many of which viewed this struggle as a jihad against the atheist Soviets. However, while some scholars credit the Soviet-Afghan War as having been a contributing factor, among many, triggering the collapse of the Soviet Union, they also acknowledge that it destabilized Afghanistan as it entered a long period of endemic fighting among warlords, which eventually led to the rise of the Taliban.

—Abraham O. Mendoza

intervention was ostensibly meant to stabilize the procommunist government, Soviet Spetsnaz forces killed Afghan president Hafizullah Amin and installed a regime closely allied to Moscow led by President Babrak Karmal. Karmal quickly set about stabilizing the countryside by stressing a return to Islam and tribal traditions as well as signing a new constitution on April 14, 1980. Karmal also suspended the social reforms that Taraki had initiated, but Amin’s brutal methods had already alienated the rural Afghan population.

Fearing the spread of an Islamic revolution, the Soviets did everything in their power to stabilize Afghanistan. They tried to influence Afghans first through massive aid and then through extensive military assistance. Yet for all the assistance

that the Soviets gave the Afghans, the Afghan National Liberation Front's jihad against the Kabul government was extended to the Soviet Union. Volunteers throughout the Muslim world joined the jihad as military and financial support from the United States, Saudi Arabia, and Pakistan strengthened the disorganized mujahideen movement. Based in Peshawar, Pakistan, the mujahideen were an alliance of seven Sunni political factions and the Shia organization Hizbi-Wahidat as well as Muslim volunteers from various countries. They initially were trained and funded by Pakistan's intelligence service, the Inter-Services Intelligence (ISI), and then later by the United States, Saudi Arabia, and the People's Republic of China.

As a result of the influx of support from the West and Middle Eastern states, the mujahideen's guerrilla campaign grew in scale and effectiveness. By 1980 the Soviets were forced to expand and deepen their involvement in Afghanistan. In an attempt to undermine and halt mujahideen, the Soviets occupied key towns where airbases, garrisons, and government centers were located. For the next five years the warfare followed a similar pattern. Typically, in the spring the Soviets would launch massive mechanized assaults into the valleys, where they would systematically destroy the infrastructure in mujahideen villages. Then in the fall and winter the Soviets would cease ground operations and concentrate on protecting their bases and encampments as well as securing strategic roads. Beginning in 1986 when the mujahideen began receiving military aid, the Afghans were able to hold their own against the Soviets; mujahideen fought the Soviet Union to a stalemate.

The ceaseless Afghan campaigns were unpopular in the Soviet Union. At about the time Mikhail Gorbachev came to power in the Soviet Union in February 1985, there was a feeling in Moscow that the Kabul regime was incapable of stabilizing the political situation in Afghanistan. Yet the Soviets sought an elusive way out of Afghanistan, desiring a unified government that would facilitate the withdrawal of troops and leave Afghanistan in the hands of a stable pro-Soviet government.

Under heavy Soviet pressure, Karmal declared a series of changes and reforms in 1985

that integrated moderate Islamists into the government. However, in April 1986 Karmal was deposed and replaced by Najibullah, the head of the secret police in Afghanistan. His appointment only increased tensions between members of the Khalq and Parcham factions as well as between ethnic groups.

In January 1987 the Najibullah regime called for a six-month cease-fire and a national reconciliation council. These were rejected by the mujahideen who, in turn, stepped up their attacks. The withdrawal of Soviet forces sealed the fate of the Najibullah regime. Najibullah clung to power until 1989, when Kabul fell to the mujahideen forces of Gulbuddin Hekmatyar and Ahmad Shah Masoud.

The Berlin Wall, 1961–1989

The Berlin Wall was erected in 1961 to prevent the exodus of escapees from East Germany (German Democratic Republic, GDR) into West Germany (Federal Republic of Germany, FGR). In the decades to follow, the wall provided a symbol of the division between the capitalist American-aligned West and the socialist Eastern Bloc under Soviet hegemony. At the end of World War II, disputes between the Soviet Union and other Allies regarding the postwar map of Europe resulted in the division of Germany into the Western-oriented West Germany and the Soviet-occupied East Germany in their respective zones of occupation. Over the course of the Cold War

(1945–1991), the issue of East Germany, particularly the divided city of Berlin (also divided into West and East) within East Germany's territory, remained a thorny issue for both the capitalist West and the socialist East. Almost immediately, the East German authorities were having trouble keeping their population from defecting to the West, causing a brain drain as many skilled workers and educated elites left for West Germany in droves, approximately 2.7 million between 1949 and mid-1961. The result was the militarization of the East German border and the construction of the Berlin Wall in 1961.

The Berlin Wall was constructed after the standoff between American and Soviet forces in the city of Berlin in 1958. Soviet premier Nikita Khrushchev chose to force the issue of Berlin by requesting that the city be transformed into a demilitarized free zone. He gave the West an ultimatum of six months (with a deadline of May 27, 1959) to negotiate directly with the East German government regarding its presence in the region. The Dwight D. Eisenhower administration, fearful of losing face in world opinion, decided not to back down on this particular issue and used the threat of military force to maintain control of West Berlin. A fresh confrontation over the city of Berlin emerged in 1961 as Khrushchev tested the resolve of the newly instated U.S. president John F. Kennedy. Kennedy and Khrushchev engaged in brinksmanship, and soon armed American and Soviet forces faced off against each other along Berlin's divide. East German minister Walter Ulbricht urged Soviet backing in the construction of the Berlin Wall to end the continuing flow of refugees into West Germany. The Berlin Wall was first erected on August 12–13, 1961.

The militarization of the Berlin Wall and the East German border resulted in the increased usage of border guards and armed military units to prevent the passage of potential defectors and escapees to the West. Observation towers, troops, border guards, barbed wire, and weapons were placed along the concrete barriers not only to prohibit entry and exit but also to display to the West the military potential of the Eastern Bloc under Soviet ideological hegemony. Utilizing the discourse of international communism, East Germany legitimized its fortification of the

A group of West Germans peer over the Berlin Wall, a barricade constructed by the East German government in 1961 that closed the border between West Germany and East Germany for 28 years. (Library of Congress)

➤ COLD WAR RELICS—EBAY AND THE CONSUMPTION OF COMMUNISM

Much as miniatures of the Bastille were popular commodities during the French Revolution (1789–1791), reminding the French citizenry of their struggle against the Old Regime, today Soviet uniforms, watches, and other memorabilia are available to Cold War enthusiasts, collectors, and die-hard old believers alike. Through eBay and other online e-commerce sites, anyone can purchase a relic to remind them of the Cold War. Chunks of the Berlin Wall, real and bogus, are available to anyone willing to purchase such a stark reminder of the greatest symbol of the Cold War and its eventual dismantling in 1989.

—Abraham O. Mendoza

borders with West Germany as a means of prohibiting the entry of subversive imperialism into the utopian workers' state. The East German Stasi police organization, utilizing a network of spies and informers in the civilian population, offered another level of internal security to prevent contacts with the West. Potential defectors were shot or maimed in the no-man's-land between the barriers of barbed wire along the border and

were immediately apprehended and subject to human rights abuses, displaying the power of the East German police state to East German citizens and Western observers. To the West, however, the Berlin Wall remained a potent symbol of the oppressive nature of communist rule. With the dissolution of Soviet authority in Eastern Europe after the policies of glasnost and perestroika in the Soviet Union, the devolution of East Germany from the Soviet sphere was imminent. In 1989, East German border guards allowed a flow of East German evacuees to enter into West Germany; this came after several weeks of problems regarding large numbers of evacuees escaping to the West through other Eastern

Bloc countries. During this wave of democratization that swept through Eastern Europe, spelling the end of communism, much of the wall was dismantled amid celebrations and fanfare. Germany became a unified nation the following year, 1990, after nearly half a century of being on the front lines of the global Cold War.

■ Introduction: Regional Conflicts

The Cold War and European decolonization unleashed waves of conflicts from 1945 to 1991, with the end of the Cold War further triggering more conflicts lasting up to the present. At the same time that the United States and the Soviet Union were attempting to assert their respective ideological worldviews across the globe, many newly independent states took sides in an effort to gain support in territorial expansion or in throwing off remaining European domination.

Regional conflicts between two powers often were independent of the ideological connotations of the Cold War and instead reflected territorial ambitions and national interests. Specific examples include, but are not limited to, India and Pakistan, China and Taiwan, Israel and Palestine, Iran and Iraq, Britain and Argentina, and Portugal and Angola. Nevertheless, they managed to become part of the geopolitical chessboard of the superpowers, with requisite financial support.

Furthermore, U.S. and Soviet interventions further triggered regional conflicts in contentious and unstable areas, such as the Horn of Africa (Ethiopia, Somalia, and Eritrea), sub-Saharan Africa (Congo and Angola), Southeast Asia (Vietnam, Laos, and Cambodia), Central Asia (Iran and Afghanistan), and Latin America (Nicaragua, El

Salvador, and Chile). While the superpowers often maintained the guise of Cold War ideological objectives, they often supported authoritarian regimes with which they had little ideological similarities.

The decade following the end of the Cold War, an era in which the United States represented the world's sole superpower, was characterized by a whole host of new conflicts that had been previously contained by the imposition of socialist regimes (Yugoslavian Civil War) or exacerbated by superpower interventions (Afghanistan and Iraq), often leading to episodes of ethnic cleansing (Bosnia and Iraqi Kurdistan). Nationalist conflicts in Africa also continued, unabated by Cold War antagonisms but imbued with ethnonationalist territorial ambitions, often resulting in ethnic cleansing and other atrocities (Rwanda, Congo, and Sudan).

The post-9/11 world has been characterized in part by U.S. unilateralist foreign policy in attempts to fulfill its perceived role as the world's sole superpower, despite international condemnation and criticism. Arguably in response to such unilateralism, the United States became one of the targets of a rise in asymmetrical warfare on the part of nonstate actors. The importance of such nonstate actors has increased. International

terrorist organizations (al-Qaeda, Hizbullah, and Jemaah Islamiyah) and transnational criminal syndicates (Mexican and Colombian drug cartels) have been able to exert their power through violence and warfare at the expense of state power. Moreover, they have been able to hold their own against the military forces of states, further triggering large-scale conflicts in their respective world regions well into the present. As of 2009 the United States is still fighting Islamist insurgencies in Iraq and Afghanistan; concurrently, Russia is reasserting its position in the Caucasus and Eastern Europe, and China has cracked down on separatist movements in Tibet and Xinjiang, illustrating that the intervention of great powers is not yet over in global geopolitics.

—*Abraham O. Mendoza*

Nationalist Movements since 1945

“Nationalist movement” is an umbrella term denoting a group of people who, believing themselves to be endowed with distinctive cultural characteristics and a shared identity, pursue political power and, often, territorial autonomy. Nationalists consider themselves to be members of a unique people, a nation, entitled to its own homeland. Such movements may take many forms: they may be liberation movements, unification movements, resistance movements, nativist movements, succession movements, or any other movement that seeks to obtain, control, or protect a piece of territory on behalf of a nation. Nationalist movements are a global phenomenon spanning every inhabited continent. Since 1945 such movements tended historically to be anti-colonial independence movements; however, even after independence has been achieved, new nationalistic aims often emerge.

In the first two decades after 1945, the bulk of nationalist movements were anticolonial or liberation movements aimed toward securing independence from imperialists and establishing independent nation-states. Decades later, the disintegration of the Soviet Union also represented a decolonization process. After the crumbling of centralized Soviet power in 1991, the former Soviet Bloc dissolved into independent nation-states: Russia, Ukraine, Belarus, Azerbai-

jan, Armenia, Kazakhstan, Kyrgyzstan, Tajikistan, Turkmenistan, Moldova, Uzbekistan, Georgia, Estonia, Latvia, and Lithuania. As in many of the former colonial holdings of the Western states, various indigenous nationalist movements in the Soviet Bloc had been agitating for independence prior to actually having it granted.

The widespread independence after World War II meant that many of the nationalist movements of the second half of the twentieth century would have goals that differed from those of their predecessors. What distinguishes the post-1945 era is the continuation of nationalist movements in a world of independent states—over half of which had not existed before 1945—and these states’ postindependence aims, which might be territorial expansion, protection of sovereignty or borders, or the wresting of territory from another nation.

For a number of reasons, nationalism has proven itself to be a remarkably enduring and flexible ideology in a world of sovereign states. For one thing, particularly in newly independent states but also in long-established Western states, the nation-state as envisioned by nationalists does not always coincide with the artificial borders of the state left behind by departing colonial powers. Thus, in some cases the failure to secure all of a perceived homeland may spur nationalist movements seeking to acquire what they believe is their nation’s rightful land. This motivation, for example, brought the North Vietnamese into open conflict with the United States during 1965–1973 as the North Vietnamese sought to reunify North and South Vietnam after the French partition. Such is also the case with the Nagorno-Karabakh region of Azerbaijan following independence from the Soviet Union in 1991. Composed of a majority ethnic Armenian population but falling within Azerbaijan borders, Armenia sought to gain control over it, leading to a three-year war between the two states that finally ended with de facto Armenian control over Nagorno-Karabakh.

Nationalist movements in independent states may also mobilize in the form of opposition or resistance to a real or perceived external threat to the national homeland. The case of Israel is one of the most clear-cut examples of this form of nationalist mobilization and certainly one of the most ongoing. Israeli nationalists are driven

by the concern that their neighbors, be they Iran, autonomous Arab states, or the stateless Palestinians in the Occupied Territories, could at any moment strike their homeland. The threat, however, need not solely be a military one. It is possible for nationalists to perceive outside threats in the form of neocolonial domination or economic exploitation, particularly in regions of the world that hold a high economic or political interest for the West even after obtaining independence. A particularly vivid example of this form of national mobilization is the Pan-Arab movement that characterized Middle Eastern politics in the 1950s and 1960s. Although the Arab states had achieved independence by this time, they still felt threatened not only by the military presence of Israel but also by what they perceived as Western, particularly U.S., attempts to meddle in Arabs' political and economic affairs.

Further, oftentimes a nationalist movement will mobilize against a minority population that it perceives as a threat. India's Hindu nationalist Bharatiya Janata Party, which had been steadily gaining seats in the Indian Parliament since 1989 until it lost the 2004 elections, espoused a radical form of anti-Muslim rhetoric, and some of its party members were accused of complicity in the violence that killed as many as 2,000 Muslims in 2002. Also, in independent nation-states, oftentimes multiple nations will find themselves in conflict over the same homeland. An especially bloody example of this type of nationalist mobilization can be found in the Rwandan Civil War of 1990–1994 between two tribal groups, the Hutus and Tutsis, that culminated in the 1994 genocide of some 800,000 Tutsis and moderate Hutus by radical Hutu militias before the Tutsi rebels finally won out.

Finally, although the second half of the twentieth century has witnessed decolonization on a global scale and the partition of the globe into sovereign nation-states, not every group that considers itself a nation has been fortunate enough to have its own homeland. Nationalist liberation movements remain, although they are now directed against states rather than empires. Basque nationalists in northern Spain, for example, have been seeking greater territorial autonomy since the late 1900s, and Tibetan nationalists

have sought independence from China since the turn of the century. Palestinian nationalists, meanwhile, also have yet to succeed in establishing a state of their own.

Regional Conflict in Africa, 1945–Present

Many of the conflicts arising from post-independence within and between African states involve the dispute of arbitrary national borders established by nineteenth-century European imperialists. Many of these conflicts also reflect the chaos and poverty that followed the collapse of colonialist regimes.

Strong irredentist elements existed or exist in the Nigerian Civil War (1966–1970); wars between Ethiopia, Eritrea, and Somalia (1972–2002); ongoing conflicts in Chad, Sudan, and the Democratic Republic of the Congo (DRC); wars in Angola (1961–1994); and wars in Mozambique (1964–1994). "Irredentist" is an Italian term applied to post-1919 Eastern Europe that refers to the feelings of people sharing a common identity who find themselves divided into rival states against which they struggle to reunite their people across international borders.

Within national borders, secession is a second threat to state integrity. It loomed large in the 1960s in Nigeria, has recurred in the DRC, and also has deep nineteenth-century roots. Even a stable country such as Senegal has its secessionist Casamance region. Somalia, owing to irredentism and secession, best illustrates the point and is today furthest from a nation-state. After Euro-

pean intervention in the 1880s, the Somalis—a clan-based nomadic Islamic people—found themselves divided into four alien-imposed states: British Somaliland, Italian Somaliland, French Djibouti, and indigenous Ethiopia. As a result, Somali patriots have since celebrated Somali heroes in four separate anticolonial struggles. The challenge by the 1960s was to build a Somali nation by reuniting peoples in different states, ruled by separate elites who had reached various compromises with three departing Western powers or who had come to uneasily coexist in Ethiopia, a country whose Christian traditions antagonized most Somalis. Djibouti was so small, so French, that until it gained independence in 1977, it remained aloof from regional tension.

As with earlier outsider interventions in Africa, Cold War interests encouraged irredentism and secession. In late 1977, searching for unity, Somalis of ex-British and ex-Italian states in Somalia took U.S. military aid, having received Soviet assistance at the start of the year. Contrariwise, Ethiopia received Soviet support at year's end, having had U.S. military aid at its start. What changed things around was a Marxist coup that overthrew Ethiopia's emperor Haile Selassie. Irredentism remained; only the rivals' global partners altered. The role of outside agencies in fomenting and arming contending factions—whether in pursuit of blood diamonds in Sierra Leone and Liberia or destabilization in apartheid's dealings with socialist Mozambique and Angola—remained key to inflaming irredentist conflicts.

While the European powers left behind few societies with the wealth, infrastructure, or education system important to maintain bureaucracies and government, none of this need acquits African politicians of military grandstanding, venal misrule, or delusional mismanagement of their economies, militaries, or regional politics. It does, however, indicate the scale of challenges that new African governments faced following colonialism. In the Nigerian Civil War, for example, the Ibo (or Igbo) of federal Nigeria's southeast attempted to secede from a recently independent republic (1960) because of the ambitions of the Ibo leader, Colonel Odumegwu Ojukwu. The pogroms that the republic waged against the Ibo in northern Nigeria and Ibo pros-

pects of enrichment from recent oil discoveries in the Niger Delta also encouraged Ojukwu. Similar motivations led to repeated secessionist attempts on the part of mineral-rich Katanga in the DRC in 1961 and 1978 and more recently in the aftermath of General Joseph Desire Mobutu's 32-year dictatorship.

The underlying causes of the Nigerian Civil War include the agreement between Nigerians and Britons in the late 1950s that a larger Nigeria would enjoy more global gravitas and the decision of British colonialists to connect a Muslim Hausa north, ill-schooled in Western ways, to a striving Christian southwest and southeast, where Yoruba and Ibo made much of their limited colonial opportunities. Exacerbating all this was the material poverty that encouraged potential fighters to desperately accept Ojukwu's beguiling promises, this after considerable suffering in their flight from northern Nigeria. The point is that it was not religion or tribalism but the colonial legacy combined with contemporary misrule that produced the Nigerian Civil War.

This is clearer if one reverses Nigeria's modern-Christian, traditional-Muslim pattern as in the Sudan. There it is a modern Muslim north that faces a disadvantaged Christian south. In describing Africa's conflicts, use of terms such as "tribal" or "ancestral" rather than "regionalism" or "irredentism" reveals the failure of outsiders to understand why Africans fight. In Nigeria, the confusion of global politics led Tanzania, France, China, and Israel to support southeast Nigeria, or Biafra, while Britain, the Soviet Union, and Czechoslovakia supported federal Nigeria. The United States was preoccupied in Southeast Asia. In most cases, regional conflicts arose as a final denouement following the breakdown of state politics.

Such is also the case in the DRC (Zaire) with current conflicts known collectively as Africa's world war. Africa's world war involves Rwandans, Ugandans, Angolans, Zimbabweans, and Moroccans as well as various Congolese groupings. Rwanda's original concern was to incapacitate *interahamwe* militias, practitioners of 1994 genocide, who had fled Rwanda into the DRC. There dictatorial misrule, Cold War politicking, and brutal early colonialism bedeviled a very fragile mineral-rich state. After the 1997 collapse

of General Mobutu's kleptocratic dictatorship—itsself a product of the chaotic decolonization that ensnared Africa in the 1960s—all Zaire's regions were fought over, as its many neighbors jealously eyed its mineral wealth. Better governance might have ameliorated some of the rivalries currently dividing peoples and states of the Zaire River basin and Great Lakes region, but the stage for tension, if not conflict, had long been set—and the dice heavily loaded against peace—by nineteenth-century Belgian, French, British, and German colonialists.

Conflicts cannot always be categorized: Nigeria's regional tragedy had a strong ethnic component and, according to Ojukwu, an anti-Ibo genocidal aspect. The terrorizing of DRC civilians follows ethnic as well as regional lines. However, Africa's regional wars follow—as did Nigeria's, as does the DRC's—patterns set out by nineteenth-century strangers who arbitrarily drew Africa's borders. The weaknesses of post-colonial states have meant that their armies usually attack their own governments rather than engage in aggression against neighbors.

African Colonial Wars

Following World War II, the Soviet Union and the United States committed themselves rhetorically to ending European colonialism. This rhetoric tallied with that of the newly formed United Nations and its Universal Declaration of Human Rights. Increased pressure on Europeans to legitimize their rule in Africa made insurgency more difficult to counter in the face of world opinion. World War II anti-Nazi resistance rhetoric was by analogy applied to anticolonialism: resistance fighters confronted local collaborators in liberated zones against which fascist methods were often deployed.

Earlier Anglo-American propaganda, especially the Atlantic Charter of 1941, had promised

the world self-determination once democracy defeated Nazi, Japanese, and fascist aggression. Winston Churchill might protest that he had not become his king's prime minister to oversee dismemberment of the British Empire, but President Franklin D. Roosevelt understood the charter as a license for free trade and liberal democracy. Budding developing world nationalists, moreover, saw it as vindication of their own calls for greater indigenous influence in colonial affairs.

Military power, furthermore, began to swing gradually but decisively against colonialism. After 1945 military strategists recognize only one large-scale antiguerrilla success: Britain's counter-insurgency in Malaysia between 1949 and 1965. By the 1970s, military aid made up the bulk of Soviet assistance to African national liberation movements. The importation of numerous cheap and reliable AK-47 assault rifles made the expense of holding African real estate greater than the benefits derived from exploiting it. At the same time, Western opinion embodied in World Council of Churches support for Southern African guerrillas encapsulated progressive opposition to racist denial of African rights.

More significantly, mid-twentieth-century world opinion swung against the nineteenth-century prejudices that had portrayed African life as cheap and justified colonial pacification: notoriously, Germany's 1906 extermination of Herero and Nama peoples in Namibia, then South West Africa. By the 1960s and 1970s, white supremacist regimes in Southern and Portuguese Africa were fighting an ideological rear guard to exploit growing belief in the United States that political instability in Africa invited communist subversion of America's colonial allies. Middle-of-the-road U.S. leaders had seen anticolonial struggles in French Indochina—from 1954 in Vietnam, Laos, and Cambodia—almost exclusively in Cold War terms. A similar tendency led right-wingers into Central Intelligence Agency (CIA) flirtation in the mid-1970s with apartheid South Africa against Cuban and Soviet forces in Angola.

One case where anticommunism and liberation rhetoric contested a more level playing field was Kenya Colony (1920–1964, before that Britain's East African Protectorate). Mau Mau insurgents of Kenya's self-styled Land and Freedom

Army opposed British settlers there from 1952 to 1960. Kenya reached independence in 1964, effectively bypassing Mau Mau freedom fighters, who were celebrated in myth rather than rewarded in fact. To Britain's relief, the Mau Mau conflict escaped serious international complications but was the last indigenous colonial conflict to do so. British expenses required in putting Mau Mau down accelerated independence but also established a black Kenyan elite opposed to subversion of Western dominance in East Africa. Quite simply, Mau Mau lacked the modern weaponry of near contemporaries, weaponry readily available to Zimbabwean, Mozambican, and Angolan guerrillas by the 1970s. Overtaken by the politics of decolonization, Britain's colonial wars ended in the 1950s. White supremacist politics and insurgent violence persisted, though, in former self-governing possessions such as South Africa and Zimbabwe.

As Africa became a cockpit for Cold War rivalries, France and Portugal fought on to maintain their colonial strangleholds. Starting at Setif in 1945, French authorities showed a brutal commitment to L'Algerie Française, paralleled only by their contemporary repression in Madagascar. From 1954 to 1962, the brutality of France's war against the Front de Libération Nationale (FLN) reflected the bitter legacy of Algeria's original conquest, the presence in Algeria of a large settler community, and the determination of France's elites to compensate for Indochinese losses. Algeria in 1960 spawned a settler-military alliance in the Organisation Armée Secrète (OAS), opposed to de Gaulle's Fifth Republic since it countenanced a negotiated settlement. The ultimate cost was more than 1 million Algerian casualties. Moreover, when the FLN did drive French soldiers and settlers (the *pied noire*) out politically, there erupted a war within the war as Algerian nationalists turned bloodily on France's former Muslim allies.

Portuguese wars in Angola, Mozambique, and Guinea-Bissau lasted well into the 1970s as Lisbon's dictatorship sought to grimly hang on to Portugal's overseas provinces. It took a 1974 military coup against Marcelo Caetano's fascist regime to end Portugal's wars in Africa. The Portuguese, North Atlantic Treaty Organization (NATO) members throughout, showed a colonial

➤ AHMED SÉKOU TOURÉ

Ahmed Sékou Touré was a radical nationalist who became the first president of independent Guinea in 1958. (Keystone/Getty Images)

Francophone Africa's more brutal equivalent to Ghana's Kwame Nkrumah, Ahmed Sékou Touré (1922–1984), led Guinea-Conakry—France's first independent black African colony—to freedom in 1958. A descendant of the nineteenth century Malinke resistance fighter Samori Touré, Sékou Touré began his career as a trade union organizer. He led Guinea's post and telegraph workers before joining the Rassemblement Démocratique Africain (RDA) in 1946. After brief service in France's National Assembly, Touré led Guinean opposition to General Charles de Gaulle's offer of a French colonial and national Union. Guinea's refusal to de Gaulle's 1958 proposal provoked a rapid French withdrawal, which Guinea only survived with the help of Soviet and Ghanaian aid.

Touré's one-party state, governed through the Parti Démocratique de Guinée (PDG), reflected his paranoid style, but despite economic mismanagement, Guinea's extensive bauxite (aluminum ore) deposits offered Guinea relative stability. Famous for his statement "We prefer poverty in liberty to riches in slavery," Touré gave his surname to African American activist Stokely Carmichael who, after immigrating to Guinea in 1969, combined it with Nkrumah's first name to become Kwame Touré. Recent investigations at Kindia have revealed mass graves dating from 1971 when Touré's oppressive rule was at its height. Guinea's current president Lansane Conde stands in Touré's shadow.

—John David Leaver

militancy eclipsing even that of the French. Portugal's secret police, the Polícia Internacional e de Defesa do Estado (International and State Defense Police, or PIDE), assassinated two guerrilla leaders, Amílcar Cabral in Guinea-Bissau and Eduardo Mondlane in Mozambique. Ultimately, it was Portugal's professional officer corps presiding over a large disgruntled conscript army that ended their country's colonial wars. At Angolan and Mozambican independence in 1975, tens of thousands of Portuguese settlers left. They were by then the only ones committed since the early 1960s to Portuguese Africa at any price.

Settlers indeed provoked liberation's bloodiest phase. Some scholars in the 1970s, however, persuaded by a Martinican psychiatrist practicing in Algeria, Frantz Fanon, argued that anticolonial wars offered ex-colonial subjects psychological catharsis and deepened the transformative potential of revolutionary violence. Persisting into the 1980s, such thinking encouraged expectations of an all-out race war in South Africa. From 1972 to 1979 Zimbabwe's liberation war, or Chimurenga, showed that on both sides violence intensified at those moments when negotiations stalled. Recent events in Zimbabwe suggest that violence offers no catharsis. Thankfully, negotiation, embittered though it was by civil strife, led South Africa to democracy in 1994, leaving anticolonial struggles to bleed over into national and regional conflict.

Middle Eastern and Gulf Wars

There have been multiple wars in the Middle East in the post-World War II era, from the Arab-

Israeli wars to the Gulf wars. While the reasons for and the circumstances surrounding these wars are distinctive, most emerged in a context of recent European decolonization.

Algerian War for Independence (1954–1962)

Because of its unique history as a settler-colony that was fully integrated into France, Algeria's long struggle for independence was also the bloodiest and most arduous war for independence in the Middle East. Since the beginning of French occupation in 1830, France had incorporated Algeria politically and economically. When faced with an independence movement, France was unwilling to release its annex. Over one million Algerians died in the struggle led by the National Liberation Front (FLN), and France finally withdrew in 1962. The FLN continues to rule Algeria but competition and conflict have emerged in recent decades. In 1991, when the Islamic Salvation Front (FIS) won numerous seats in an election, the FLN canceled the elections, and civil war followed; in 2000 the FIS's armed faction, the Islamic Salvation Army disbanded, but violence has not completely ceased. In 2006 an al-Qaeda branch in Algeria began a series of kidnappings and bombings of government and Western-linked targets.

North Yemen's Civil War (1962–1970)

In 1962 a military coup overthrew North Yemen's Shia ruler, Imam Muhammad al-Badr, and civil war broke out as al-Badr tried to regain power. Both the military regime and royalists obtained foreign aid in the conflict; Egyptian president Gamal Abdel Nasser provided some 70,000 troops to the military regime, and Saudi Arabia supplied the royalists with arms. The war ended in 1970, and the opposing sides agreed on a conservative republic. Nasser's involvement in the war is sometimes called Nasser's Vietnam, as he made no apparent gains.

The next few decades saw volatile relations between North and South Yemen. North Yemen had been an independent monarchy since the end of the Ottoman Empire following World War I,

MIDDLE EAST

➤ KURDISTAN—MINORITY IN THREE COUNTRIES

Kurdistan is an area in the Middle East populated mostly by Kurds that covers areas of northwestern Iran, northern Iraq, eastern Turkey, and small regions of northern Syria and southern Armenia. While not an independent nation-state, there is still some level of common cultural traits that characterize this transnational region, with its only politically autonomous region being Iraqi Kurdistan. Due to their ethnicity and religion, the Kurds have come into conflict with each of the major states within which Kurdistan exists. During the Iranian Revolution (1979–1982), holy war was declared against Kurdish rebels by Ruhollah Khomeini, stamping out the rebellion in Iranian Kurdistan. During the Iran-Iraq War (1980–1988) and after the First Gulf War (1990–1991), Iraqi leader Saddam Hussein ordered attacks against Iraqi Kurds, who were deemed traitors to Iraq in both conflicts. In Turkey, while Kurds are an important sector of Turkish society, they are also seen as a threat to the unity of the Turkish state, particularly given the recent violence of the secessionist Kurdistan Workers' Party (Partiya Karkerên Kurdistan, PKK) against the Turkish state.

—Abraham O. Mendoza

while the southern part of Yemen was a British Protectorate until 1967. After Britain's withdrawal, a radical Marxist state emerged, which was a unique phenomenon in the Middle East. In the 1970s hostilities and unification talks occurred intermittently, and throughout the 1980s the two states were wary of each other; finally in 1990 North and South Yemen united into one state.

Lebanese Civil War (1975–1990)

The underlying reasons for Lebanon's violent civil war are rooted in its unique confessional political system that was established under French colonial rule. After Lebanon's full independence from France in 1946, the power dynamics of the representative government remained based on the ratio of Christians to Muslims that was de-

termined by the 1932 census; cabinet members were selected on a more specific sectarian basis. Lebanon's population is extremely diverse, with 18 officially recognized religious sects, and its main groups are Shia, Sunni, and Maronite Christian. In the late 1960s, some Muslims began demanding a new census to reflect Lebanon's accurate demographics. Maronites still held the most power in government, but Muslims outnumbered them, and Shia Muslims had long surpassed Maronites as Lebanon's largest religious group.

In the early 1970s, as Lebanon was already dealing with increasing tensions among its diverse religious groups, the Palestine Liberation Organization (PLO) moved its base to southern Lebanon. The PLO's relocation, and particularly its rivalry with Maronite paramilitary groups, was a central factor in Lebanon's descent into civil war in 1975.

The already complicated war became further entangled with Syrian, Israeli, and American interference, which escalated fighting among Lebanon's various sectarian militias. Muslims and others who felt alienated by the current political system tended to side with the PLO; the Maronites' main militia was supported first by Syria and later by Israel. The war did not officially end until the Taif Agreement of 1989, which left Syria in virtual control of Lebanese politics until Syria finally withdrew its forces in 2005. Once a country where diverse religious groups lived quite well together, the Lebanese Civil War intensified sectarian identities and divisions.

Iraq-Iran War (1980–1988)

Relations between Iran and Iraq were tenuous leading up to the Iran-Iraq War after Iran had supplied arms to Kurdish insurgents in Iraq during the 1970s, but the countries had signed a treaty in 1975. After Iran's 1978–1979 revolution, however, the new Islamic Republic of Iran promoted the spread of Islamic rule in the region and particularly encouraged Iraq's Shia community to revolt. Moreover, Kurds had utilized the chaos of Iran's revolution to resume attacks against Saddam Hussein's government; when Iran harbored Kurdish rebels in violation of the 1975 treaty, this renewed animosity with Hussein's sec-

ular regime. In 1980, Hussein invaded Iran in an attempt to overthrow the fledgling Islamic regime while Ayatollah Khomeini was still consolidating control.

Hussein's intended incursion swelled into an expensive eight-year war in which over half a million lives were lost by its end in 1988. The war ended with no apparent gains to either side in terms of territory or political standing.

Gulf Wars (1991, 2003–)

The First Gulf War of 1991 began when Iraq invaded Kuwait in 1990, on account of long-standing and recent border disputes, Hussein's political ambitions, and his massive debt after the war with Iran. After Iraq ignored pressure by the United Nations (UN) to withdraw, American president George H. W. Bush, unwilling to let Hussein control the oil-rich Gulf, formed a coalition among most of the Arab states. After bombing Iraq for 42 days, Bush declared Kuwait liberated in February 1991. The consequences of the war were devastating and extensive for the Iraqi people. U.S. air strikes and UN economic sanctions continued throughout the 1990s, while programs such as the notorious Oil for Food provided little for ordinary Iraqis.

In 2003, the United States invaded Iraq due to inaccurate intelligence that Iraq was hiding weapons of mass destruction from UN inspectors, who had been authorized to search Iraqi sites after the 1991 Gulf War. Hussein had thrown out inspectors in 1998 but allowed them to resume inspections in 2002. Despite their return, President George W. Bush invaded Iraq in the face of the UN's objections and international outrage. Iraq's weakened state after UN sanctions and the superior U.S. military ensured a successful conquest; the occupation, however, has encountered numerous difficulties. Even though a constitution was passed in October 2005, resistance groups remain active, and Iraq still lacks security and continuous basic services.

Algerian Wars of Liberation

The French-Algerian War, which lasted from 1954 to 1962, was one of the postwar world's most brutal and protracted struggles. Power returned to the southern Mediterranean's majority Muslim population at Algerian independence, when France was finally driven from North Africa.

L'Algerie Francaise, the notion that Algeria was an integral part of France, took hold after 1830 and endured among most of the French until 1962. It took the overthrow of France's Fourth Republic in 1958 and the return of Charles de Gaulle to a reinvigorated national presidency to begin the slow process of extracting France from its Algerian quagmire. Algeria, having been one of France's initial conquests, proved to be the last of its substantial possessions to achieve independence. Estimates of total fatalities over eight years of conflict range from 350,000 to one million. These deaths continue to haunt both France and Algeria.

France became involved in Algeria in 1830 when Charles X's restored royalist government refused to pay grain debts owed to the Algerian Dey by Napoleon Bonaparte following his 1798 invasion of Egypt. Charles X, his regime in trouble, turned a minor diplomatic incident, when the Dey struck a French consul, into pretext for an invasion of Algeria. France, however, initially struggled to conquer Algeria. Until the late 1840s Abd al-Qadir, an Islamic holy man, maintained effective opposition to French armies, which numbered in the hundreds of thousands. These armies controlled only a narrow coastal strip and only occasionally penetrated inland in exhausting and vulnerable flying columns. As late as 1870 a major uprising in the Kabylie Mountains threatened French power in Algeria.

► THE PIEDS NOIRS OF ALGERIA

French Algerians, also known as *pieds noirs* (black feet), were descended from European settlers and considered French nationals in the context of the Algerian War (1954–1962). While a considerable number of them were French settlers, many of them were descended from settlers from Spain, Italy, and other places in the Mediterranean, among them Sephardic Jews. Pieds noirs constituted 10 percent of the population of French Algeria, and a sizable proportion of them were in support of French control of Algeria, with a tiny minority advocating independence for Algeria. With the end of the Algerian War, the pied noirs were faced with the grim realization that France would not continue the struggle, and most decided to repatriate to France. Approximately 1 million pieds noirs left for France, with most of them settling in southern France particularly around Marseilles. Others migrated to Spain, North America, Australia, and Israel, among other places. Many of them had never been to France, and while they did consider themselves French, they did not think of France as home. While pieds noirs have adapted and assimilated to French society, some express the sentiment of having been displaced from the homeland of their ancestors.

—Abraham O. Mendoza

Thereafter settlers from the northern side of the Mediterranean arrived in numbers. Once these so-called *pied noirs* constituted ten percent of Algeria's population, a French presence was secure. This lasted until France's colonial empire was undermined by military defeats, first at the hands of the Nazis and later by colonial nationalist movements. Among the European settlers in Algeria was existential novelist and philosopher Albert Camus. An influential liberationist residing in Algeria was Franz Fanon, the psychiatrist from French Martinique who became a theoretician of cathartic violence. Throughout the 1950s, the long struggle in Algeria against the secularist forces of the Front de Libération Nationale (FLN) did much to inspire the pessimism of postmodernist and existentialist French thinkers such as Jacques Derrida, Jacques Lacan, Michel Foucault, and Albert Camus.

Ironically, many *pieds noirs* (literally “black foot” in English, a derogatory label aimed at the original poverty of those seeking wealth in a land they dominated as a racial minority) were not even French. When Algerian conflict began in 1954, Spaniards, Italians, and Maltese made up a large proportion of the 1.1 million *pieds noirs*. During the early phase of the war this group attacked traitors to L'Algerie Francaise. De Gaulle's willingness to negotiate with Algerians and subsequent Algerian independence helped the *pied noire* to convert a governor-general, raise a military coup (initially supportive of de Gaulle), and finally challenge de Gaulle's Fifth Republic through a terrorist army, the Organisation Armée Secrète (OAS).

In contrast, FLN opposition to France became a cause célèbre for Third World liberationists, including Egypt's Gamal Abdel Nasser. From the 1945 massacre of Muslims at Setif by French police and *pieds noirs* to the Philippeville counter-massacre of Europeans in 1955, many on both sides showed a readiness to take lives when necessary. When FLN *maquis* (guerrillas) took the fight into Algiers city in 1961, Jacques Massau's French paratroopers terrorized the terrorists, inspiring the classic liberationist cinematography of *The Battle of Algiers*. By 1962 when de Gaulle succeeded in extricating France, perhaps 200,000 Muslims had fought alongside 400,000 French conscripts against possibly 50,000 FLN guerrillas. Almost 600,000 *pieds noirs* and perhaps 120,000 of France's Muslim allies soon after left Algeria for France. The Algerians paid a substantial price but finally gained control of their own country.

In 1965 Algeria's military took control from civilian FLN leaders, ending divisions that had afflicted the country's freedom fighters throughout their struggle. In so-called café wars perhaps 5,000 Algerians in France lost their lives in intra-nationalist faction fights. Meanwhile, France's Muslim allies, the *barkis*, struggled to integrate into a French society long accustomed to ignoring its North African communities. By 1991 when Islamists appeared to have won Algeria's presidential elections, the Algerian military annulled the elections, plunging the country into civil war. Today under President Bouteflika, Algeria is emerging from a secular-Islamist conflict that

for more than 20 years has torn the country apart. France meanwhile is now home to Europe's largest Muslim population and, as the 2005 Muslim youth riots illustrated, has yet to successfully integrate many members of these communities into its national culture.

Arab-Israeli Conflict

Zionism, which originated as a reaction to pervasive East European anti-Semitism as well as from the nationalist sentiments of Central and West European Jewish thinkers, emerged in the late nineteenth century and culminated in the declaration of a Jewish state in Israel, at that time British Palestine, on May 15, 1948. The Arab-Israeli wars that ensued over the next 60 years have had major impacts on both regional and international politics.

During the first Arab-Israeli war (1948-1949) the nascent state, enjoying superior military numbers and organization but lacking first-rate military equipment, successfully fought off the invading Arab armies from Egypt, Lebanon, Jordan, Iraq, and Syria. The Israelis turned the tide in this war only after receiving arms from Soviet-backed Czechoslovakia, as the United States refused to sell weapons to any involved parties. Both the United States and the Soviet Union, however, had immediately recognized Israel following its declaration of independence.

The 1948 War, known in Israel as the War of Independence and among Palestinians and some Arabs as the Nakba, or "Catastrophe," resulted in the new state gaining legitimacy to its borders, at least to those outside the Arab world. On the Palestinian side, this conflict resulted in the

creation of a massive refugee crisis, as at least 700,000 Palestinians fled to neighboring Arab states with the hope of returning home following the anticipated Arab victory. The Israeli government, press, and many academics have long claimed that the Palestinians fled their homes at the behest of Arab governments and radio broadcasts. Recent research, however, has shown that in many instances the Israeli military used armed force or scare tactics in order to remove these people from their homes. Other serious by-products of this war include the beginning of the secondary Arab boycott of Israel, which meant that the Arab nations refused to trade with the new state, and the expulsion of many Jews from Arab countries, most notably Iraq. Finally, the Arab military defeat in this war contributed in some part to regime changes in parts of the Arab world, as Jordan, Syria, and Egypt all suffered through either assassinations or coups in the years immediately following the 1948 War.

By 1956 the Israelis enjoyed a growing economy and arms shipments from Europe but experienced a worsening of relations with the Soviet Union, which had begun championing Arab causes in the region in hopes of breaking the Western stranglehold in the Middle East. In 1955 the Soviets, again through Czechoslovakia, signed a significant arms deal with Egypt, now controlled by the Free Officer Movement under the direction of Gamal Abdel Nasser. While the Israelis feared that the new arms deal would soon allow Egypt to wage war on the young state, the British and the French were even more upset with Nasser after he nationalized the Suez Canal and ordered all foreign troops out of Egypt. Following this event, France and England approached Israel regarding possible military action against Nasser, and the three nations eventually agreed on a course of action. The Israelis would attack Egypt on the pretext, which was valid, that Egypt was refusing to allow Israeli vessels to pass through the Suez Canal, an international waterway. Following this the British and the French were supposed to call on both sides to stop fighting. The Egyptians were expected to refuse this order, at which point the French and the British had planned to attack their forces. On October 9, 1956, Israel invaded the Sinai Peninsula in Egypt, thus allowing Britain and France

➤ YASSER ARAFAT

Yasser Arafat was the leader of the Palestine Liberation Organization (PLO) from 1969 to 2004 and the president of the Palestinian Authority from 1996 to 2004. Praised by some for his central role in placing Palestinians' rights on the United Nations (UN) agenda and denounced by others for the PLO's endorsement of violent resistance before 1988, Arafat was a controversial figure throughout his life. Even among Palestinians, he has a mixed legacy; their perceptions of his image range from the legitimate spokesman of the Palestinians to an obstacle to peace and a corrupt politician.

Arafat was born in Gaza in 1929 and earned his engineering degree in Cairo. In the late 1950s, he founded al-Fatah, an exile group that aimed to recover Palestine via armed struggle. After Israel's victory in the 1967 war, Palestinians lost confidence in the Arab states, while al-Fatah gained popularity with its emphasis on establishing an independent Palestinian state. In 1969, Arafat was chosen to lead the PLO, an umbrella organization of groups with various ideological strains; since then he has been the predominant symbol of the Palestinian cause.

Despite receiving a Nobel Peace Prize in 1994 for his efforts in the Oslo Accords (1993 and 1995) along with Israeli leaders Yitzhak Rabin and Shimon Peres, the peace process all but ended with the Second Intifada in 2000. Throughout most of the intifada until his death in 2004, Israel confined Arafat to his compound in Ramallah under house arrest while blaming him for all militant resistance waged against its occupation. Israel's fear of him becoming a martyr certainly enabled him to die a natural death, yet Palestinians revere his memory and continue to flock to the Muqata, his burial site in Ramallah.

—Elizabeth Brownson

to issue their ultimatum. When, as anticipated, Egypt refused to comply, Britain and France began bombarding Egyptian positions. The United States and the Soviet Union both reacted angrily to this course of action and, following Britain and France's entry into the war, agreed to impose sanctions on all three aggressor nations. This conflict therefore marked the beginning of the end of major British involvement in the re-

gion. Although the United States and the Soviet Union reprimanded Israel, it had scored a major military victory over Egypt and had established a strong relationship with France that would last until 1967. The war also bought Israel a decade of peace that it used to build up its forces and gain further international allies. Oddly, the 1956 war marked a rare moment of cooperation between the two superpowers, as the Soviets hoped to capitalize by portraying themselves as a non-imperialist power in the region, and the United States attempted to distance itself from its allies' actions.

Although the early 1960s witnessed inter-Arab conflicts, it was not until 1967 that Israel and several Arab states again went to war. Encouraged by the Soviet Union and angered by taunts from other Arab states claiming that he had not done enough to help the Palestinians in their struggle against Israel, Nasser engaged in a game of brinkmanship with the Jewish state. He ordered the United Nations peacekeeping force, which had resided in the Sinai Peninsula in between Israel and Egypt, out of the country and moved his forces into this region. Furthermore, he began to boast that Israel would soon be destroyed, thus evoking, in the imaginations of many Israelis and Jews around the world, still recent memories of Hitler's war on the Jewish people. Nasser also, in direct violation of the conditions that he agreed to following the 1956 war, again closed Egyptian waters to Israeli shipping. Although it is unknown if Nasser actually intended to go to war with the Jewish state, on June 5, 1967, Israel simultaneously attacked Egypt, Syria, and Jordan, wiping out each nation's air force before they had a chance to counterattack. Thus the war, although it continued until June 10, 1967, was basically won on the first day.

The 1967 war irrevocably altered Middle Eastern and international politics. Israel, which emerged as the best-organized and most powerful nation in the region, dealt what turned out to be a death blow to the spread of the radical secular-Arab nationalism embodied by Nasser. The Jewish state also doubled its territory, acquiring the West Bank from Jordan, Gaza and the Sinai from Egypt, and the Golan from Syria and uniting Jerusalem for the first time since the British mandate. Israel would later give Sinai back

to Egypt as part of the terms of the 1979 Camp David Peace Accords but remains in control, at least militarily, of the other conquered areas. Following the 1967 War, Israel lost its major supporter, France, which distanced itself from the Jewish state possibly in order to curry favor with the Arabs. Israel, however, gained a new primary backer, the United States. An additional result of this war was another exodus of Palestinian refugees escaping the Israeli advance in the Jordanian-occupied West Bank. Following the 1967 War, the Palestinian national movement gained new life as Yasser Arafat's Fatah faction took over the Palestinian Liberation Organization (PLO). This war also led many in the Arab world to renounce secular nationalism as the path to global success and eventual victory over Israel and instead to turn to Islam as the answer. Finally, the 1967 War brought Israel greater international Jewish support, especially from American Jews, and also inspired many evangelical Christian groups who believed that Israel's reunification of Jerusalem was an apocalyptic signal that Jesus would soon return to earth.

During the late 1960s and early 1970s Israel and Egypt engaged in what is referred to as the War of Attrition. These border skirmishes resulted in a prolonged period of heightened tensions in the region but little more. By 1973 many Israeli civilian and military leaders had grown overconfident in their nation's position in the region and thus ignored reports of possible threats from their neighbors. At this time Egypt, now ruled by Anwar Sadat, and Syria, ruled by Hafez al-Assad, were secretly planning a new war against Israel. While it is difficult to assess Asad's ultimate goals beyond recapturing the Golan, it is evident that Sadat did not expect to win the war but rather hoped to regain some of Egypt's prestige by winning early battles. This, he believed, would eventually force Israel to the negotiating table and might bring about peace in the region. Egypt and Syria attacked Israel on October 6, 1973, during the Jewish holiday of Yom Kippur, and thus this war is known in Israel as the Yom Kippur War. Israel was, for once, caught off guard and struggled to mobilize its forces. After suffering significant casualties during the initial fighting, Israel, aided by a massive American supply lift, regrouped and systemati-

cally pushed back the invading armies, which had also been resupplied by a Soviet air lift. Before they could capture Egypt or Syria's capitals and destroy their armies, the United States and the Soviet Union pressured the warring parties into signing a cease-fire agreement.

Unlike the other Arab-Israeli wars, the 1973 war led Israel to reconsider its options in the region. The first postwar casualty was Golda Meir, Israel's prime minister, who left office under pressure from constituents who blamed her for Israel's initial problems in the war. A key international development during this war was that Arab oil-producing countries including Saudi Arabia used OPEC as a political tool by refusing to supply oil to Western nations that were aiding Israel. This marked the first time that Arab oil-producing states succeeded in seriously disrupting oil supplies to the West and touched off the first of several global energy crises during the 1970s. By the end of the decade Israel and Egypt would sign the first peace agreement between the Jewish state and an Arab country. Syria and Israel, however, would come into conflict a decade later.

The next major Arab-Israeli conflict occurred in the midst of the Lebanese Civil War of the 1980s. On June 6, 1982, Israel invaded southern Lebanon in order to seek out and destroy Yasser Arafat's PLO leadership. Lebanon in this period had been torn apart by sectarian battles between its Maronite Christian, Sunni Muslim, Shiite Muslim, and Palestinian refugee communities. Israel entered the conflict on the side of the Maronite Christians but also hoped to gain support from Shiite communities in the south of Lebanon. Syria, which had long considered Lebanon to be in its direct sphere of influence if not part of its country, was also active in Lebanon in this period and came into conflict with the Israelis inside and outside of Beirut. The Israelis eventually forced the PLO leadership, including Arafat, to leave Lebanon for Tunisia but also suffered through both public relations and military disasters. While helping their Maronite allies hunt down alleged terrorists, the Israelis allowed a Phalangist (Maronite militia) faction to enter the Palestinian refugee camps of Sabra and Shatila, where the militia engaged in a massacre of men, women, and children. While Israelis did not take

part in this event, there is no doubt that they aided the Phalange in its attack. This conflict also saw the beginning of the radical Shiite organization known as Hizbullah, which used suicide attacks and guerrilla warfare against its Christian and Israeli enemies and later against American marines stationed in Beirut. The rise of Hizbullah in Lebanon also allowed the Iranians, the largest predominantly Shiite nation in the world, the ability to interfere in Lebanese domestic politics.

Although the period 1984–2006 did not witness reconciliation between Israel and the majority of the Arab world, outside of the Israeli-Palestinian conflict that continues to rage on it has been a period of relative peace, at least compared to the previous 36 years. Most of the conflicts in this region since this time have been between other states or have involved external actors such as during the First and Second Gulf Wars.

Middle East Peace Process

The Middle East Peace Process refers to the diplomatic efforts to establish permanent peace and normal relations between Israel and the Arab world since the early 1990s. As a response to the series of wars that have plagued the region since 1948, these have included separate efforts at reconciliations between Israel and the Palestinians, Jordan, Lebanon, and Syria. Egypt was the first Arab country to sign a peace treaty with Israel in 1979, which occurred under the leadership of Egyptian president Anwar Sadat and Israeli prime minister Menachem Begin and was mediated by U.S. president Jimmy Carter. Since then, Jordan

has been the only other Arab country to sign a peace accord with Israel. It did so in 1994 under the collaboration of King Husayn and Israeli prime minister Yitzhak Rabin. While it is the Oslo agreements of 1993 and 1995 between Israel and the Palestine Liberation Organization (PLO) that are the most evocative of the phrase “the Middle East Peace Process,” peace talks are now on hold because conditions have deteriorated significantly since 1995. Although Ehud Barak and Yasser Arafat attempted to revive peace negotiations in 1999, those efforts failed and have been shelved since the outbreak of the Second Intifada (uprising) in 2000.

Conflict between Israel and the Arab states dates to Israel's declaration of independence in 1948. Hostilities between Jews and Palestinians began gradually in the late nineteenth century as Jewish immigrants started settling in the unoccupied areas of Turkish-ruled land, which was then predominantly Arab Palestine. Jewish immigration stemmed from violence against Jews in Russia and the rising appeal of Zionism in Europe. During the period of British rule (1920–1948), the Jewish population of Palestine increased from about 12 percent in 1914 to about 32 percent in 1946 largely due to the need to relocate survivors of the Holocaust. The influx of Jewish immigrants during the 1930s who sought to escape the rising power of Nazi Germany in Europe exacerbated tensions between the Jewish and Arab communities.

Fighting ensued immediately after the British withdrew from Palestine in 1948 and Jewish forces defeated the Palestinians and Arab states. During the war, most of the Palestinian community was displaced as Arabs heeded the call of their leaders to leave, causing the entire region to face a major refugee crisis. Out of approximately 860,000 Palestinians, only about 130,000 were allowed to stay in Israel. The rest moved to refugee camps, including 470,000 Palestinians who had fled or were expelled to the West Bank and Gaza; these territories came under Jordanian and Egyptian control, respectively, until the 1967 war, when Israel captured and subsequently occupied them. The other approximately 257,000 displaced Palestinians were taken in by Arab states, mostly Jordan, Syria, and Lebanon.

After the unprecedented peace treaty between Egypt and Israel was signed in 1979, there was an impasse in terms of further peace talks until the 1990s. In the wake of the First Intifada of 1987–1991, which contested Israel's occupation of the Palestinian territories and human rights violations, and the first Gulf War, the United States and the Soviet Union sponsored peace talks in Madrid, Spain, in 1991. The Madrid Talks consisted of separate meetings between Israel and Jordan, Syria, and Lebanon; the PLO consented to have its interests represented by the joint Palestinian-Jordanian panel. After several rounds of negotiations, the talks amounted to little before the 1993 talks in Oslo were made public. The secret negotiations at Oslo resulted in mutual recognition between Israel and the PLO and gave Prime Minister Rabin and Arafat a starting point to begin official peace talks, which enabled Jordan and Israel to sign a peace treaty in 1994. Rabin and Arafat agreed to create an elected Palestinian Authority (PA) to govern Palestinians in the Occupied Territories (OT) and also agreed to Israel's phased withdrawal from occupied areas but postponed discussions on the difficult issues of Israeli settlements in the OT (which are illegal according to international law), Palestinian refugee compensation, and the status of Jerusalem until a later date.

A devastating blow to the peace process came when Yigal Amir, an extremist Israeli Jew, assassinated Rabin one month after the 1995 agreement in Oslo. Benjamin Netanyahu, the Israeli prime minister during 1996–1999, denounced Oslo, promised not to turn over any land to Palestinians, and continued building settlements in the OT. Under Barak's government in 1999–2000, there was a renewed attempt to reach an Israeli-Palestinian accord with U.S. president Bill Clinton's assistance.

While Barak's talks with Arafat had not resolved every issue, they at least provided hope to Israelis and Palestinians alike. Both sides, however, claim that the other had undermined these negotiations. The Palestinians charge that Ariel Sharon's provocative visit to Haram ash Sharif, a sacred space for Muslims adjacent to the holy Jewish Western Wall, accompanied by 1,000 Israeli police officers was meant to harm the peace process. This event angered a large number of

Palestinians, many of whom took to the streets to begin the Second Intifada. On the Israeli side, many argue that Arafat had never intended to make peace, which was why he refused a generous offer by Barak and, in their opinions, resorted to violent struggle. It should be noted that since whatever Barak did or did not offer Arafat remains unknown, the truth of this definitive event remains hidden. In any event, Sharon soon rose to power, and he along with Arafat and Hamas (the most powerful Islamic party in the Palestinian territories) continued to undermine peace efforts. While Sharon regained some credibility with his unilateral pullout of Gaza in 2005, numerous critics suspect that his motives were to leave this area in order to consolidate Israel's position in the West Bank.

India and Pakistan since Partition

The India-Pakistan wars were a series of four regional conflicts between the two countries following their partition (as constituent parts of British India) and independence from British rule in 1947. Three of these wars were centered on the contested territory of Kashmir, while the 1971 dispute concerned East Pakistan, modern-day Bangladesh. Tensions between the two countries remain high, justifying immense military expenditures by both sides extending to the development of nuclear weapons. In the Cold War context, the United States and China typically aligned themselves with Pakistan to prevent the development of India as a major regional power, providing diplomatic support and weapons systems. In turn, the Soviet Union provided

diplomatic support to India. While India declared itself to be a nonaligned power in the Cold War, it sought Soviet economic support in its struggle against Pakistan.

After World War II, Britain officials in Westminster had effectively decided to leave India due to its waning economic importance and Britain's domestic financial troubles. In previous decades, British authorities had countered Indian opposition to their rule by supporting the Muslim League against the Indian National Congress, which represented the Hindu majority of British India. The Muslim League supported Brit-

ish authorities, hoping to gain their own Muslim state (Pakistan) after independence. However, by playing both sides against the other, Britain ensured that the religious divide shaped political attitudes in the future. In 1947 Britain finally relinquished control of the Raj (British India) and gave India its independence, partitioning British India into Muslim Pakistan (West Pakistan and East Pakistan) and Hindu India. However, this led to a massive exchange of populations and dissatisfaction regarding the resulting land distribution, particularly centering on the province of Kashmir.

The source of the multiple conflicts is a dispute over the mountainous region of Kashmir and the way the destiny of the region was handled by the two countries following partition in 1947. At the time of partition, Kashmir, populated mostly by Muslims, was ruled independently by the Hindu Maharaja Hari Singh until an invasion by Pakistanis forced him to cede his dominions to India. Pakistan argued that Singh had only done this after succumbing to pressure from India. This situation ignited the First Kashmir War in 1947 between regular Indian and Pakistani troops. Lasting for more than a year, the war was characterized by both sides as making significant incursions into each other's territory. However, when the war ended with a United Nations (UN) cease-fire, India had managed to secure a major portion of Kashmir.

The Second Kashmir War of 1965 began when Pakistan played a role in igniting rebellions, known as Operation Gibraltar, in the contested provinces of Jammu and Kashmir among Indian Muslims against Indian authorities. Pakistan hoped to create a major rebellion to justify an armed intervention in support of their fellow Muslims. However, India retaliated by launching an attack on Pakistan, effectively triggering the larger war. By September 22 of that year, the UN Security Council called for a cease-fire from both nations. Nonetheless, the cease-fire lasted only six years before the Indo-Pakistani War of 1971.

The Indo-Pakistani War of 1971 was associated with the Bangladeshi war of independence, a conflict between West Pakistan and East Pakistan (Bangladesh). India supported the East Pakistanis in their struggle for independence against West Pakistan through various diplomatic efforts and humanitarian aid. After months of increasing tensions between India and Pakistan due to the increased military buildup on their respective borders, Pakistan finally attacked India on December 3, 1971. The Indian military defeated the Pakistanis in Bangladesh, and major combat operations then focused on West Pakistan. A mere two weeks after India entered the war, the Pakistanis surrendered, suffering heavy casualties, huge materiel losses, and the secession of East Pakistan, now the newly independent nation of Bangladesh.

➤ MASS KILLINGS IN BANGLADESH, 1971

Bangladesh was formerly a province of greater Pakistan on the eastern side of India with a sectarian Bengali independence movement seeking the creation of their own state. During the Bangladesh War of Independence from Pakistan, widespread killings of civilians by Pakistani forces and local religious militias resulted in an estimated 200,000–3 million civilian casualties. In addition, Bangladeshi intellectuals throughout the country were systematically murdered by religious militias at the instigation of Pakistani forces. Following the invasion of Pakistani forces many Bengalis, mostly Hindus persecuted by Muslim militias and the Pakistani army, sought refuge in neighboring India, which was Pakistan's major regional rival. India's entry into the war resulted in the defeat of Pakistan and the secession of Bangladesh. To this day, scholars, politicians, and survivors still debate whether this violent episode in 1971 should be considered genocide.

—Abraham O. Mendoza

The fourth Indo-Pakistani war, also known as the Kargil War, took place in 1999 in the Kargil district of Kashmir. The direct cause of the war was the infiltration of Pakistani troops and Kashmiri rebels on the Indian side of the Line of Control, which served as the defensive perimeter of Indian territory for the Indian military. Indian military forces attacked the enemy positions and forced a Pakistani withdrawal. The situation triggered major instability within the Pakistani government and economy, resulting in the 1999 coup d'état by General Pervez Musharraf.

Decades of suspicions and antipathy have led both Pakistan and India to increase their military striking power. This has resulted in vast military expenditures on their military organizations and weapons systems, particularly nuclear weapons. Both sides have also solicited assistance from outside powers in their efforts. Pakistan has been a staunch ally of the United States, enabling Pakistan to secure weapons and financial assistance to meet the Indian challenge. Pakistan also has a friendly stance with China, which also has border disputes with India. In contrast, India relied primarily on the auspices of the Soviet

Union (until 1991) for diplomatic support and assistance. In recent years, Pakistan has remained a valuable ally for the United States in terms of its support against global terrorism and through its provision of bases for operations into Afghanistan in support of the NATO offensive in response to the September 11, 2001, attacks. However, India also has recently forged stronger diplomatic and economic links with the West after enacting neoliberal trade policies in the 1990s, opening it to investment from Europe and the United States.

Sino-Soviet Conflict, 1956–1989

Beginning in the mid-1950s, the relationship between the Soviet Union and the People's Republic of China (PRC) deteriorated rapidly, this

despite the fact that since 1950 Moscow had provided significant financial, technological, and scientific assistance to Mao Zedong's regime. Weakening relations culminated in a public split in the early 1960s. The Sino-Soviet rift destroyed the myth of a monolithic world communism and had major ramifications for the Cold War, creating a new military rival and foreign policy distractions for the Soviet Union while offering diplomatic opportunities to the United States.

The rift between Moscow and Beijing first appeared during 1956–1959. Friction ensued when Soviet leader Nikita Khrushchev's de-Stalinization campaign, his policy of peaceful coexistence vis-à-vis the United States, and his refusal to assist China in building atomic weapons converged with Mao's aspirations for recognition as Josef Stalin's successor in the communist world and his boasts that China could achieve socialism more quickly via a path different than that followed by the Soviet Union. In 1960 the split became open as the respective leaderships exchanged insults and accusations publicly. At a major communist congress (May 1960) in Bucharest, Romania, Khrushchev characterized the Chinese as "left adventurists" who recklessly risked unleashing a third world war. Later (November 1960) at a communist conference in Moscow, convened to heal the Sino-Soviet break, the Chinese accused the Soviets of revisionism, while Khrushchev charged Mao with dogmatism. In the years immediately following, animosity grew as the Chinese lambasted Khrushchev for his handling of the Cuban Missile Crisis (October 1962), for his refusal to support them during their war against India (1962), and for his signing of the Limited Nuclear Test Ban Treaty (August 1963). Beijing also demanded that Moscow relinquish those territories, specifically the Soviet Maritime Provinces, that the tsarist regime had extorted from the Qing dynasty in the mid-nineteenth century, exacerbating the situation.

Neither Khrushchev's dismissal in October 1964 nor Mao's death in 1976 improved relations. In March 1969 animosity reached a dangerous flashpoint when Soviet and Chinese military forces engaged in brief but heavy fighting near disputed territories in the Amur-Ussuri region. This clash sparked firefights at other points along

➤ BORDER CLASHES

Escalating tensions between China and the Soviet Union, as a result of ideological differences regarding the international revolution as well as old unresolved border disputes, resulted in a series of border incidents between the Red Army and Chinese forces. In March 1969, Chinese troops attacked Soviet border guards on Zhenbao Island, which resulted in Soviet retaliation concentrating on Chinese positions along the Ussuri River. In August of that year, along the Sino-Soviet border in the Chinese province of Xinjiang, Soviet troops inflicted heavy casualties on Chinese troops. These skirmishes increased the likelihood of warfare, with some concerns that either side might use nuclear weapons. However, cooler heads in Moscow and Beijing decided on diplomacy and negotiation in September 1969, ending the threat of a potential war over disputed borders.

—Abraham O. Mendoza

the 4,000-mile Sino-Soviet frontier that produced significant casualties and mutual recriminations. In light of what was viewed as an extremely unstable situation in the East, the Brezhnev leadership, which had succeeded Khrushchev in 1964, deployed 40 divisions supported by nuclear weapons along the frontier with China while simultaneously making a renewed commitment to achieve détente with the West, the latter policy exemplified by the willingness to accommodate West German chancellor Willy Brandt's Ostpolitik (1970-1974), to enter into the SALT I agreement (1972) with the United States, and to sign the Helsinki Accords (1975). Simultaneously, Beijing established relations with the United States (1971), which resulted in Washington's formal recognition of the PRC.

During the late 1970s and early 1980s, relations between the USSR and the PRC arguably reached their lowest point. Soviet support for Vietnam's December 1978 invasion of Kampuchea (Cambodia) that toppled Pol Pot's pro-Chinese Khmer Rouge government, China's brief February 1979 invasion of Vietnam ostensibly in retaliation for the latter's attack against Kampuchea, the Soviet Union's December 1979 invasion of Afghanistan, and the continued presence of substantial Soviet forces along the frontier with China combined to keep tensions high and the situation along the Sino-Soviet frontier extremely unstable. Mikhail Gorbachev, however, Soviet general secretary from March 1985, began the process of normalizing Sino-Soviet relations.

The architect of perestroika and glasnost, Gorbachev actively sought improved relations with Beijing, proclaiming this goal publicly and negotiating a series of commercial and educational exchange agreements during his first months in office. Subsequently, Gorbachev removed all major obstacles, as defined by China, to Sino-Soviet reconciliation, ending the Soviet Union's war in Afghanistan, persuading Vietnam to withdraw from Kampuchea, and reducing Soviet troop deployments along the border with China. Gorbachev's efforts culminated in a May 1989 visit to Beijing, which, though complicated by student protests, signaled the end of the Sino-Soviet split and the beginning of a new era in Russo-Chinese relations.

China-India Conflict

As ancient civilizations, China and India coexisted in peace for millennia, with the Himalayas separating the two empires and political contacts minimal. Culturally, Hinduism and Buddhism spread from India to China (and then to Korea and Japan), and this spread completely transformed Chinese society and culture. Nevertheless, as modern nation-states in the late twentieth century, with the exception of the early 1950s, Sino-Indian relations have been characterized by border conflict, regional rivalry, and strategic, military, and economic competition.

The Sino-Indian border conflicts resulted from the rejection by Beijing of the British-drawn McMahon Line of 1913-1914 separating India and Tibet, the flight of the Dalai Lama to India after the 1959 Tibetan Uprising, and the dispute following the 1962 border war in which China seized 38,000 14,670 square miles (square kilometers) of Indian territory in Aksai Chin and another 2,000 square miles (5,180 square kilometers) of northern Kashmir that Pakistan had ceded to Beijing under a 1963 pact.

China sought to confine Indian power to the region of South Asia in order to avoid confronting a powerful neighbor south of the Himalayas. Beijing was extremely concerned when India permitted the creation of the Dalai Lama's exiled government in Dharamsala. In response, China decided to contain India by supporting Pakistan in the 1965 Indo-Pakistani War. Throughout the 1970s and 1980s, the continuous Chinese arms transfers to Pakistan indicated the close links between Beijing and Islamabad.

The Cold War conflict further complicated the Sino-Indian relations, as shown in the Soviet alliance with India and the U.S. support for China since the 1970s. Despite the gradual development

➤ SINO-PAKISTANI RELATIONS AND INDIA

The regional rivalry between Pakistan and India, following the partition of 1947, has shaped Pakistani relations with the People's Republic of China. Given China's frosty relationship with India in regard to border disputes and outright armed hostilities in 1962 (Sino-Indian War), Pakistan's relationship with China became one of mutual support vis-à-vis India. Following partition, India sought friendly relations with China, seeking Chinese participation in the Non-Aligned Movement against the bipolar Cold War superpowers. However, the Sino-Indian War ended any possibility of such support. Furthermore, Chinese backing of Pakistan, in the form of supplying weapons, money, and diplomatic support against India, further soured relations between India and China. By the late 1960s, the Sino-Soviet split led to better relations between the Soviet Union and India to better counter the solidarity of China and Pakistan in Central Asian regional affairs.

—Abraham O. Mendoza

of Sino-Indian rapprochement after Indian prime minister Rajiv Gandhi's visit to Beijing in 1988, Beijing refused to sacrifice its strategic partnership with Pakistan. It is this two-front threat (Pakistan in the west and China in the north and northeast) that gave rise to Indian concern about China's policy in South Asia. With the end of the Cold War and the American military involvement in Iraq and Afghanistan, the United States becomes an active factor in the balance of power among China, India, and Pakistan. Because of the new quadrangular structure, the Indo-Pakistan-China interactions also have become part of the tension between the United States and China over Taiwan and North Korea.

Another security issue affecting Sino-Indian relations is the rise of Chinese naval activity in the Indian Ocean. To protect its lines of communication across the Indian and Pacific oceans, China gradually expanded its naval activity in the region throughout the 1990s. China constructed new ports, maritime communications, and overland transport routes in Pakistan and Myanmar. Underlying China's agenda is the need

to strengthen Pakistan in order to maintain the balance of power in South Asia.

In response to the perceived Chinese encirclement, India launched its countermeasures by pursuing security relations with China's neighbors in the Pacific Ocean, especially Vietnam, Japan, and Taiwan. New Delhi's counterencirclement was a direct response to China's expansion of its security ties with India's neighbors in South Asia. The entangled relations between China and India indicate each country's security concerns as they continue to compete with each other in the wider Asian region.

China-Taiwan Conflict

The present conflict between the People's Republic of China (PRC, or China) and the Republic of China (ROC, or Taiwan) is rooted in the Chinese Civil War (intermittently fought between 1927 and 1949). As Guomindang (GMD) Nationalist forces, under Generalissimo Jiang Jieshi (Chiang Kai-shek), were forced from mainland China by PRC forces, they retreated to the island of Taiwan as their tentative base of operations. The subsequent international recognition of Taiwan as the Republic of China, particularly by the United Nations (UN), and the PRC's contrasting view of Taiwan as a renegade province show how both sides were unwilling to recognize the other's independence. This rivalry quickly took on Cold War coloring as Taiwan became a staunch U.S. ally, leading to small acts of brinksmanship between PRC and ROC forces. New constellations emerged in the early 1970s when U.S. president Richard Nixon extended a conciliatory rapprochement to the PRC.

Chinese Nationalist leader Jiang Jieshi represented China during wartime and postwar conferences held by the major Allies of World War II, even as his forces were losing the war to the Chinese communists in the late 1940s. This allowed the ROC to receive international recognition as the sole representative in the UN for China, with a seat on the Security Council and the associated international legitimacy. However, the reality was that by 1949, most of China was well under the control of Chairman Mao Zedong of the Chinese Communist Party (CCP), who saw the existence of Taiwan as tentative and to be rectified in the future by an eventual PRC conquest. In addition, the GMD in Taiwan refused to recognize the CCP's control of mainland China as permanent, leading both sides to abide by a one-China policy that would guide their relations for the rest of the century.

The emergent Cold War antagonisms between the United States and the Soviet Union and between the United States and the PRC had a significant impact on Chinese-Taiwanese relations. U.S. support for Taiwanese independence strengthened the ROC's position and ensured its survival. However, it also prompted small skirmishes between ROC and PRC forces, mainly over islands in the Taiwan Straits (Formosa Sea) that separated China from Taiwan, as the islands of Matsu and Quemoy, occupied by ROC forces, were contested twice. Two major Taiwan Straits crises, one in 1954–1955 and the second in 1958, were instances in which ROC forces held on to these islands while undergoing shelling by PRC artillery and small-scale amphibious invasions. These skirmishes ensured staunch U.S. support of Taiwan and led to the opening of the Sino-Soviet split as China began to detect a lack of support coming from Moscow.

In the 1970s U.S. president Richard Nixon, wishing to take advantage of the emergent Sino-Soviet split, began negotiations with the PRC for international recognition and its seat in the UN. During this time, both the PRC and the ROC were still at odds over Chinese unification. However, the GMD's dictatorial hold over Taiwan's domestic politics and repressive regime had alienated the ruling party from most of the island's inhabitants. The development of the Democratic Progressive Party (DPP) in 1989, in opposition to

➤ TAIWAN AND THE KOREAN WAR

In reaction to the escalation of events in Korea, driven by efforts by the communist North to subdue the capitalist South, the fiercely anti-communist Nationalist government of Taiwan (Republic of China) requested participation in the resistance against this act of aggression. The United States, which was effectively leading United Nations (UN) forces in the upcoming struggle, refused to allow Taiwan to participate, fearing that this would ensure the entry of the People's Republic of China into the conflict on the side of the North. However, President Harry S. Truman sent the U.S. Seventh Fleet to protect Taiwan from a potential Chinese attack. This further complicated the matter, which was formerly seen as primarily an inter-Chinese problem, by bringing in the United States as guarantor of Taiwanese independence. As Taiwan tied its fortunes to American support, it also soured its relationship with the mainland, becoming a contentious hotspot during the Cold War.

—Abraham O. Mendoza

the GMD's policy of one China, has gained since in popularity as the Taiwanese have developed a sense of national identity as Taiwanese rather than as Chinese. In spite of the growing economic and diplomatic links between the two countries since the 1980s in the form of massive investment, travel permissions, and conciliatory meetings, as the DPP grows in political popularity, mainland Chinese hostility in the form of increased missile defenses and naval strength continues to prevent a lasting peace.

Falkland Islands War (1982)

The Falklands War was a 72-day war between Argentina and Great Britain over control of the

➤ MARGARET THATCHER AND THE FALKLAND ISLANDS WAR

British prime minister Margaret Thatcher, rides aboard a British tank at Fallingbommel, West Germany, on September 17, 1986. Mrs. Thatcher was making an official visit to British forces. (AP Photo/Joel Fink)

Grim economic problems beset British prime minister Margaret Thatcher in her early years in office, making her unpopular among many in the British public. Her free market and privatization policies had alienated much of the population, particularly the hard-pressed working class. However, the outbreak of the Falkland Islands War (1982), which galvanized British public support and a newfound sense of national pride, assisted in Thatcher's growing popularity. Despite British casualties and what was deemed by international critics as a minor war for a small contested colony by both Britain and Argentina, the conflict resulted in an outpouring of British patriotism and increasing support for Thatcher's Conservative government. As a result, the British Conservative Party held the majority in the House of Commons in the 1983 elections, maintaining Thatcher at the helm in the office of prime minister.

—Abraham O. Mendoza

Falkland (Malvinas) Islands. The Falklands War officially began on April 2, 1982, when Argentina landed thousands of troops on the islands and ended on June 14, 1982, when Argentina surrendered to British forces. The war was the product of a long-running dispute between Great Britain

and Argentina over the Falkland Islands, or the Malvinas as Argentina called them. The Falklands are a rugged collection of islands in the South Atlantic some 300 miles off Argentina's coast. Britain frequently intervened in the region in the early 1800s and had been in continuous possession of the Falklands since 1833. Argentina repeatedly protested the British presence, although the Argentine dictator of the 1830s and 1840s, Juan Manuel de Rosas, offered to sell the Falklands to Britain. Britain refused to pay for what it already possessed.

Through the decades, Argentina never renounced its claim to the Falklands. Sporadic negotiations between Britain and Argentina in the 1970s yielded some progress but no substantive agreement on the key issue, namely sovereignty over the islands. The Argentine government attempted to entice the United States into backing its position by claiming that British possession of the Falklands violated the Monroe Doctrine; however, the United States rejected the application of the doctrine to the Falklands case, arguing that Britain had a claim that antedated its seizure of the islands in 1833. During much of the twentieth century, the United States maintained only a marginal interest in the controversy.

The dispute over the Falklands came to a head in 1982. Argentina had long expressed disenchantment with what it considered the slow pace of negotiations with Britain. The approach of the 150th anniversary of the British takeover also played a part in the Argentine decision to resort to force. Growing domestic opposition to military rule encouraged some in the military leadership to conclude that a move against the Falklands would help unite the country behind the regime. Military action would also be a distraction from the sorry state of the Argentine economy. The Argentine leadership doubted that Britain would move militarily to prevent seizure of the islands.

In late March 1982 U.S. intelligence reports indicated that Argentine forces appeared to be preparing for an invasion of the islands, prompting a lengthy telephone conversation on April 1 between U.S. president Ronald Reagan and Argentine president General Leopoldo Galtieri. Reagan warned Galtieri that an invasion would compromise U.S.-Argentine relations and provoke a mili-

tary response by Britain. Nevertheless, Argentina invaded on April 2, quickly subduing a small detachment of British Royal Marines.

Britain responded diplomatically and militarily. The British convinced the European Economic Community (EEC) to impose economic sanctions on Argentina and the United Nations (UN) Security Council to condemn the invasion and call for an Argentine withdrawal. Britain dispatched a large military contingent to retake the islands by force if necessary. The United States responded with a spurt of shuttle diplomacy led by U.S. secretary of state Alexander Haig. Haig made the diplomatic rounds of London and Buenos Aires trying to broker an agreement based on a cease-fire, Argentine withdrawal, and a commitment to negotiate on the long-term status of the islands.

Haig's shuttle diplomacy soon unraveled as the negotiations demonstrated America's pro-British position. American efforts at mediation ended on April 30 when the United States announced that it was imposing economic sanctions on Argentina and would provide military assistance to Britain, although there would be no direct U.S. military involvement. British forces landed en masse in the Falklands on May 21, 1982, resulting in another meeting of consultation of North and South American countries under the Rio Pact. The meeting passed a resolution—with the United States abstaining—that condemned Britain for its “unjust attack on Argentina” and called upon the United States to lift its economic sanctions on Argentina and end its assistance to Britain. With little substantive diplomatic action, the struggle for the Falklands would be determined by military action alone.

The lopsided conflict came to a predictable conclusion with the surrender of Argentine forces on June 14, 1982. Argentina sustained 655 killed in action, while Great Britain suffered 236 killed in action.

The Falklands War was more a colonial war than a Cold War conflict, but it certainly had Cold War implications. First, the Reagan administration lost one of the strongest supporters of its anticommunist policies in Central America. Second, the crisis strengthened ties between Argentina and Cuba, which had prominently supported the Argentine position. Finally, the crisis produced widespread doubts about the role the United States played in mediation efforts, especially given the rapid U.S. switch from quasi-impartial mediator to supporter of Britain. In addition, in the wake of the war, two of its most prominent players lost their positions. The Argentine military regime was humiliated, bringing a return to civilian rule in 1983 and the prompt resignation of President Galtieri. Secretary of State Haig resigned on June 25, 1982, partially as a result of his controversial role in the crisis. Only British prime minister Margaret Thatcher benefited politically from the war, as it raised her sagging popularity and ultimately led to her success in upcoming elections.

■ Introduction: Ethnic Cleansing and Genocide

Ethnic cleansing is defined as a policy by which governments, military institutions, or armed combatants relocate and remove members of specific ethnic, racial, or religious communities deemed enemies of the state, coercing them to seek asylum elsewhere or be threatened by the potentiality of extinction, that

is, genocide (the actual deliberate act of annihilating people of a particular group). The apparent goal of ethnic cleansing is to create a more homogenous state for the national identity group in power. Ethnic cleansing not only involves the actions of the perpetrators against the victims but is also a larger dynamic, as it can only be

successful with the complacency of the international community and institutions such as the United Nations (UN) or North Atlantic Treaty Organization (NATO) that are often unwilling to involve themselves in ending the bloodshed.

Article II of the 1948 UN Convention on the Prevention and Punishment of the Crime of Genocide (CPPCG) defines genocide as “any of the following acts committed with intent to destroy, in whole or in part, a national, ethnical, racial or religious group, as such: killing members of the group; causing serious bodily or mental harm to members of the group; deliberately inflicting on the group conditions of life, calculated to bring about its physical destruction in whole or in part; imposing measures intended to prevent births within the group; [and] forcibly transferring children of the group to another group.” Written as a response to the mass murder of an estimated six million European Jews (the Holocaust) committed under the German Third Reich during World War II, this convention stipulated the characteristics that delineated genocide as a crime against humanity and was therefore illegal under international law. This convention failed to apply to the genocide of the *Volkdeutsche* Germans (ethnic Germans, many of whom had resided in Eastern Europe for centuries) as they were expelled, abused, and murdered in great numbers (an estimated two million) in Eastern Europe from 1948 to 1951.

The euphemistic term “ethnic cleansing” entered the English language and international discourse in the 1990s to describe the acts perpetrated by Serbs on Muslim minorities in the context of the Yugoslavian Civil War. Within this upheaval in the Balkans, the term developed as a less objectionable way to refer to genocide on the part of the Serbs. The contested origin of the term is typically attributed to the Serbo-Croatian term *ciscenje* to describe policies of making the nation pure of minority national groups and was widely disseminated through the global news media. The term was used to avoid the type of morally objectionable (and legal) connotation carried by the term “genocide” and its association with crimes against humanity as defined by international law. Various critics allege that the term was popularized by the U.S. public relations agency Ruder Finn to characterize Serbian ac-

tions in Kosovo as akin to the Holocaust to gain world support for Albanians.

Widespread ethnic cleansing policies have occurred at various times in many world regions after 1945, often with minimal international intervention. In the 1960s and 1970s, the ethnic cleansing policies of Indonesia and Congo toward minority populations were dismissed in the West as postcolonial internal affairs, thereby achieving a negligible international response and ignoring the tenets of international law regarding genocide. In the late 1990s, the ethnic cleansing policies enacted in Rwanda, in Yugoslavia, and in the province of Darfur in the Sudan have gathered much attention. The Rwandan genocide committed by the politically and militarily dominant Hutus led to the deaths of 500,000 Tutsis and the exodus of 2 million. The Serbian destruction of vast segments of the Bosnian Muslim population of Sarajevo and later the persecution of the Albanian Muslim population of Kosovo garnered little response from the European Union but led to international outrage and NATO intervention. The crisis, still ongoing as of 2009, in the Darfur province of southern Sudan, with black Sudanese being murdered at the hands of Muslim fundamentalists from the north, while attaining much international attention, has nonetheless failed to ignite an assertive response from abroad other than much severe international condemnation.

Indonesian Ethnic Conflicts

The Republic of Indonesia has a very diverse population. It is home to hundreds of ethnic groups speaking approximately 200 distinct languages and dialects. But since Indonesia won independence from Dutch rule in the 1940s, it has been a unified state with a single national identity. It has, however, had problems with conflict between various Indonesian ethnic groups; some of these conflicts even threatened the existence of the unified nation-state.

These conflicts are based on a variety of divisions within Indonesian society. Muslims have clashed with non-Muslims, and there have also been disputes among Indonesian Muslims over how their religion should be practiced. Conflicts

have sometimes assumed a regional dimension. Minority populations perceive the Javanese, who make up some 40 percent of the population, as having dominated the country both politically and economically. The Javanese have also been seen as having defined the nation in a manner that assumes that an Indonesian identity is in fact a Javanese one. Feelings of regional resentment might be related to the fact that several regions have unique relationships with the national narrative. Aceh, Irian Jaya, and East Timor were all brought into the Indonesian nation-state in unique ways. Furthermore, ethnic Chinese, who came to Indonesia during colonial times, have had a complex and troubled relationship with the rest of the Indonesian population.

Starting with the attempt by Ambonese Christians to set up an independent republic in the Moluccas in 1950, Indonesia has had a series of regionally based rebellions. The West Java-based Darul Islam movement violently agitated to make Indonesia an Islamic state until the capture of its leader Kartosuwiryo in 1962. In 1956–1957 discontented military officers and politicians staged revolts in Sumatra and Sulawesi. These rebellions were prompted by unhappiness with the regime of President Sukarno rather than with the desire to separate from Indonesia and were largely suppressed by the end of 1958. Violent clashes between the army and local guerrillas took place in Aceh in the 1950s and from 1991 until 2004. Armed resistance to incorporation into Indonesia took place in East Timor from 1975 until 1999, when *de facto* independence was achieved, and has occurred on a much lesser scale in Irian Jaya from the 1970s until the present day.

Communal violence has also long marred Indonesia. Anti-Chinese riots have occurred at regular intervals and have been fueled by the widely held belief that the Chinese had an unfair economic advantage, which they used to exploit other Indonesians. At the same time Chinese Indonesians, systematically kept out of mainstream society, were until recently subject to discriminatory legislation and were largely barred from careers in the military and politics. As another example, in the late 1990s clashes took place in Kalimantan between Madurese, who had settled in the region with government encouragement,

➤ INDONESIA—THE NEXT YUGOSLAVIA?

The 1990s witnessed the breakup of the multiethnic Yugoslav federation, an event accompanied by a great loss of life. The disintegration was connected to an economic downturn and the death of dictator Josip Broz Tito, who had provided a strong unifying hand. In 1998 the downfall of Suharto and perhaps a parallel breakup scenario for Indonesia occurred. Democratic institutions were slow to gain strength, and the economic crisis that had helped end the Suharto regime continued. There was also the temptation on the part of some politicians and military officers to stress religious and ethnic differences among the population in order to consolidate their personal power. East Timor voted to leave Indonesia in 1999, while the government continued to suppress an insurgency in Aceh, and communal fighting broke out in the Moluccas. Terrorist attacks in Bali and Java in 2002 and 2003 threatened to earn the country a reputation as a haven for violent religious radicalism. But the inevitability of the breakup scenario may have been exaggerated. Political institutions have strengthened. The 2004 presidential elections were deemed by outside observers to have been a great success. Fighting has stopped in the Moluccas, and a peace settlement has recently been signed in Aceh. Most Indonesians, according to recent public opinion polls, are committed to a national identity while being proud of local ethnic and religious roots.

—Michael Wood

and indigenous Dayak, who felt that their land and way of life were under threat. Javanese and Balinese soldiers and officials stood by powerless as thousands were murdered, and numerous refugees fled the island.

In the Moluccas, violent battles raged between Muslims and Christians from 1999 until 2002. The population had lived together in peace for centuries, but economic pressures along with competition for political patronage drove communities apart. Conflict was associated with increased religious self-awareness and the presence of outside agitators. Factions of the Indonesian military openly sided with the participants in the fighting, and the radical Laksar

Jihad recruited volunteers in Java to aid Muslim combatants. Conflicts within and between Indonesian ethnic groups have been costly in terms of loss of life and property. However, such losses are dwarfed in magnitude by those caused by purely political violence. The killings associated with the destruction of the Indonesian Communist Party and the rise of Suharto in 1965–1966 may have claimed half a million victims.

Despite the troubled history of ethnic and communal conflict in Indonesia, the country has held together remarkably well. Only areas such as East Timor, Irian Jaya, and Aceh that have a radically different connection to the development of the nation have taken the opportunity to break away. For most of the populace, there seems to be little interest in entirely placing ethnic identity before national identity. Communal violence has largely ended in the Moluccas, although scattered killings continue in Sulawesi. The status of the ethnic Chinese has improved, with Chinese politicians serving in the cabinet and Chinese festivals openly celebrated. However, there have recently been some troubling signs of village-based intolerance in Java, with local hostility directed at members of the Ahmadiyya Muslim community, at charismatic Javanese sects, and at Christians living in predominantly Muslim areas.

Rwanda

On the night of April 6, 1994, a genocide lasting 100 days began in the small central African country of Rwanda. This state-sponsored and systematic mass murder of Africans defined as Tutsis and any politically moderate Hutu elements of the population left more than 800,000 dead and 2 million more displaced as refugees. Many world leaders dismissed this obvious genocide as merely an ancient and inherent tribal conflict. However, there is no evidence of ethnic

conflict in Rwanda's history prior to German and Belgian colonial rule.

By the late nineteenth century a complex centralized state had developed in Rwanda, and definitions of ethnicity were quite loose. The kingdom was ruled through an intricate web of client-patronage relationships. Wealthier members of the aristocracy were loosely associated with the term "Tutsi." The term "Hutu" was roughly defined as "subject" or a marker of socioeconomic status and was not the cultural definition commonly associated with ethnicity. People in Rwanda spoke the same language (Kinyarwanda), practiced similar traditions, and intermarried across the fluid lines of Tutsi and Hutu. However, these terms hardened into more rigid classifications under European colonial rule.

Beginning in 1894, Rwanda experienced nearly 70 years of foreign rule under first German and later Belgian colonial domination. Rwanda's complex government contradicted racist notions of African inferiority common among Europeans at the time. Witnessing that loosely defined Tutsis held many of the positions of power in government, European officials grasped onto a corrupted version of Rwanda's oral traditions in an effort to explain their conundrum. Some local traditions stated that the Tutsis were cattle-herding foreigners who had migrated to Rwanda from Ethiopia or North Africa. While it is true that a population had migrated to Rwanda from the southern Sudan several hundred years before, this group had been assimilated into the local culture by the twentieth century and did not define the Tutsi social class. Nonetheless, the corrupted theory was instituted as historical fact and came to be called the Hamitic Myth. This myth presumed that Tutsis were descendants of a superior race of foreign invaders who conquered Rwanda and subjugated the masses of people defined as Hutus. The myth was taught in schools and became reinforced as European colonialists chose Tutsi individuals as their local government agents. The roughly 15 percent of the population labeled Tutsi, mainly on the basis of economic wealth, were favored under the colonial system. They were given the best jobs and were provided with the limited social and economic benefits associated with European rule. By the 1930s, Rwandans were required to carry identity cards listing one's

ethnicity, firmly institutionalizing the importance of the terms “Hutu” and “Tutsi” in Rwandan society.

By the 1950s, the Belgian colonial rulers knew that independence was imminent in Rwanda and worried that the minority Tutsi population, whom they had supported, would not maintain political control. In an effort to protect Belgian interests in the country, support for a ruling Tutsi minority was abandoned and shifted to a dominant Hutu government. This resulted in the Tutsi minority being viewed as the scapegoats for the injustices of the colonial period as the two groups competed for power. In the wake of these power struggles, the country witnessed its first examples of ethnic violence in the late 1950s and early 1960s.

From independence in 1962 until 1994, Rwanda was controlled by an increasingly radical government dominated by a small clique of Hutu elites. A government propaganda campaign heightened social tensions and often blamed Tutsis for the struggles faced by the nation. Quotas were established in schools and in government institutions, reserving the majority of positions of power for Hutus. Many Tutsis fled the country as refugees throughout the early years after independence in an effort to escape persecution. By the late 1980s, Rwanda had fallen on hard economic times, and the government was heavily dependent on foreign aid. At the same time, Tutsi refugees began organizing outside Rwanda. In 1990 a Tutsi-dominated force called the Rwandan Patriotic Front (RPF) invaded. Over the next four years civil war waged between the RPF and the Hutu government.

By April 1994, the United Nations brokered a fragile power-sharing agreement between the RPF and government forces; however, tensions were still high. The spark that set off the genocide was the assassination of Rwanda’s president, whose plane was mysteriously shot down in the country’s capital on April 6. Massacres began immediately and spread out from Kigali across the countryside. The killings were systematic and rapidly orchestrated. Many in the international community failed to publicly recognize the genocide and did little to stop it. During a period of 100 days Rwanda was engulfed in violence that would leave up to 85 percent of the Tutsi

> NYARUBUYE

Staff and pupils murdered at the Catholic school and convent at Nyarubuye, Rwanda, by Hutu militia on May 15, 1994. (Sam Kiley/Sygma/Corbis)

In rural eastern Rwanda there is a Catholic church and school called Nyarubuye. In the early days of the 1994 genocide, thousands of local Tutsi fled to the church for sanctuary from the massacres. They were encouraged to do so by their local mayor, Sylvestre Gacumbitsi. Tragically, they were not spared. Led by the same local mayor, a large group of militia came to Nyarubuye, and over the course of several days as many as 20,000 men, women, and children were murdered in the parish compound.

Churches such as Nyarubuye had historically been places of sanctuary during times of trouble in Rwanda. Unfortunately, those orchestrating the genocide also knew this, and the horrific scenes that played out in Nyarubuye were replicated at many different churches around the country. In some cases Church officials actively resisted and tried to save the victims, while in other instances members of the clergy were among those who organized the killings. Today Nyarubuye remains much as it did in the immediate aftermath of the genocide. The unburied remains of victims still lie on the parish floor, with the evidence of genocide distinctly visible. Nyarubuye remains in this state for a reason. It is a contemporary memorial, a monument of shame, a way to never forget the horror of genocide in Rwanda.

—Matthew Carotenuto

population dead; also killed were thousands of Hutu who opposed the genocide. Ultimately the RPF ended the genocide. As of 2007, the RPF's controversial general, Paul Kagame, led the country in efforts to rebuild and reconcile Rwanda's troubling past.

Sudanese and Congolese Civil Wars

The Sudanese and Congolese civil wars were both based on enduring ethnic conflicts that erupted following the decolonization of these and other African territories in the late twentieth century. Both the Sudan and Congo gained independence during the first wave of African nationalism (1940s to 1960s), yet neither had developed a strong national identity by the time independence was achieved. In both countries, civil wars broke out as various factions attempted to gain power to either build a national identity or retain distinctive regional and ethnic identities. The conflicts began when secessionist groups attempted to break away from the new states while the central governments attempted to retain the colonial structures and borders. The conflicts also were complicated by external influences related to the Cold War.

In the Sudan, armed conflict between the culturally distinct northern and southern regions began in 1955 on the eve of independence. The north was predominantly Arab and Muslim and had maintained close cultural ties to Egypt. The south was predominantly black and Christian or animist with cultural ties to ethnicities in northern Uganda. The regions had been administered separately by the British empire until 1946, when

northern and southern Sudan were merged into a single administrative unit.

Following the granting of independence in 1956, scattered elements of resistance in the south were put down using military force, but this only seemed to strengthen the resolve of the resisters and further polarize Sudanese society. By 1963 a group calling itself Anyanya had unified many of the southern ethnic groups in a guerrilla war against the Sudanese government. Anyanya gained strength, declaring the independence of southern Sudan in 1967. In the north, coups and countercoups plagued the government at Khartoum, weakening central authority and political legitimacy. In 1972 Sudanese president Jafar Nimeiri negotiated an agreement with Anyanya, granting amnesty to the rebels and regional autonomy.

In the 1970s Nimeiri embarked on an effort at nation-building through a series of socialist reforms, which began to infringe on the provisions of the 1972 agreement. In 1983, faced with the rising strength of the Islamist element of Sudanese society, Nimeiri imposed Sharia (Islamic law) on the entire state, including the previously autonomous southern region. A second civil war broke out, and Khartoum faced further instability until Omar al-Bashir seized power in 1989. The southern forces, predominantly represented by the Sudan People's Liberation Army (SPLA), maintained control of a significant portion of the southern third of the Sudan. Distinct but related conflicts subsequently erupted in northern Uganda and in western Sudan (Darfur).

The Congolese conflict originated shortly after the Congo became an independent state in June 1960. Within months the new government faced secessionist movements in the resource-rich Katanga and South Kasai provinces. The power struggle soon drew in the involvement of Cold War opponents, as Premier Patrice Lumumba appealed for external support and both the United States and the Soviet Union sought to influence the newly independent state. Belgian paratroopers and a United Nations (UN) force deployed to the Congo and a UN-brokered peace agreement ended the fighting with the separatists of Katanga Province in 1963. In 1965 the Congo was dominated by Cold War politics. Mobutu Sese

Seko seized power in a coup supported by the Central Intelligence Agency (CIA), while Che Guevara attempted to galvanize rebel leader Laurent Kabila for the socialist camp.

Over the next several decades, Mobutu transformed the Congo into a corrupt and oppressive single-party state, while Kabila continued to bide his time in the eastern jungles of the Great Lakes region. In the 1970s and 1980s Mobutu began a program of Zaireanization and economic development that fell far short of expectations but was propped up by the United States because Zaire, as the Congo was then known, supported a CIA-sponsored faction in the Angolan conflict.

With the end of the Cold War, the Western financial and military support for Mobutu dried up. The Great Lakes refugee crisis of 1994–1996 proved more than the decaying Mobutu regime could handle, and Kabila was in a position to take advantage of this situation. Supported by both Uganda and the Tutsi government, which had come to power in Rwanda in the aftermath of the 1994 genocide, Kabila marched on Kinshasa and deposed Mobutu in 1997.

The establishment of the Democratic Republic of Congo in 1997 did not end the conflict because the questions of power distribution were still unresolved. Kabila's attempts to reduce foreign (Rwandan) interference in the Congo sparked a second civil war in 1998. This renewed conflict essentially divided the Congo into three parts: the regions controlled by Kabila loyalists, a pro-Uganda faction, and a pro-Rwanda faction. Two bilateral peace agreements ended the conflict with Uganda and Rwanda in 2002. Following Kabila's assassination in 2001, a transitional government of the Congo was formed in 2003. As of 2009, fighting continued in the eastern and southeastern provinces.

Ethnic and Genocidal Wars in Africa

Outsiders to Africa have long misconstrued ethnicity as tribalism. Ethnicity refers to subnational identity within a nation containing many such identities. People who acknowledge a common culture based on language, sanctioned behaviors, ritual, spiritual beliefs, and distinct attitudes toward life share an ethnicity. Tribalism is not a term usefully applicable in Africa. Belief in tribalism, however, has sustained conflicts in which one side or other has made unsubstantiated charges of genocide. Genocide is the effort to exterminate an entire ethnic group. There was, for instance, no genocide of Ibo people by a northern-dominated federal government in Biafra, in southeastern Nigeria, in the mid-1960s. Not all such charges are spurious, but readiness to recoil at supposed barbarism has exacerbated conflicts by drawing outside sympathies one way or another. The world is often too ill-equipped, too easily distracted, and too ready to respond superficially to African conflicts.

This proved the case, despite United Nations principles outlawing Nazi-style atrocities, during the 1994 Rwandan genocide. Hutu and the Tutsi identities emerged from colonialism in Rwanda ruled first by the Germans from 1895 and then by the Belgians after 1919. Both colonial powers propagated Hamitic myths, according to which taller, supposedly lighter-skinned pastoral people had moved south to establish hegemony over shorter, apparently darker-skinned agricultural people. So-called Hamitic pastoralists were identified as Tutsi, while their agricultural subordinates were identified as Hutus. The colonial ethnographers responsible for this theory badly mixed up culture, race, and language. Hamitic does not refer to race but instead only to a linguistic branch of an Afro-Asiatic language family that also includes Arabic and Hebrew. Although

Tutsis long dominated Hutus—*ububake* and *umubeto* are terms that anthropologists use for their precolonial patron-client relationships—it was the Belgians who, by favoring Tutsi over Hutu, fossilized Rwandan identities. Sharpened identities, which few scholars acknowledge as distinct ethnicities, thereafter nurtured post-colonial conflict and ultimately genocide.

When Belgian colonialism ended in 1959–1960, the Hutu overthrew the Tutsi, and many Tutsi refugees fled to neighboring Uganda. More than communal hatred, though, would be required for genocide. By the 1980s Rwanda's economy was in a perilous state. Coffee, the country's major export, earned record low prices. This accelerated rural migration to Kigali, the capital, where urban unemployment grew. The ruling Hutu government mobilized unemployed youths into militias known as *interahamwe* (those who fight together) or *impuzamugambi* (those who fight with a single aim). With unwitting outside connivance, these young men, many simple civilians, responded to a campaign on state radio of hatred by joining with army units and murdering between 800,000 and 1,000,000 Tutsis and moderate Hutus from April to July 1994. UNIMIR, the UN force in Rwanda at the time, proved powerless, although it had been told to supervise an earlier cease-fire by rebel Tutsi-dominated forces attacking the extremist Hutu government.

Government propaganda about Tutsi rebels of the Rwandan Patriotic Front (RPF) convinced many Hutus that it was kill or be killed. Appeals from Canadian UNIMIR commander Romeo Dallaire fell on deaf ears. President Bill Clinton's State Department performed verbal gymnastics to avoid the word "genocide," the term triggering UN responsibility for intervention. Indeed, with extremist Rwandese officials sitting on the UN Security Council, UNIMIR forces were actually scaled back. Ultimately only an RPF victory ended the genocide, but even that triggered French intervention to establish a safe zone into which fearful Hutu refugees, some mass murderers, fled. As the RPF established itself, Hutu *interahamwe* forces attacked the new government from the Democratic Republic of the Congo (DRC). There the RPF pursued its enemies in a spreading regional conflict that some have called Africa's first world war.

Few doubts have been raised about the world's shameful response to the Rwandan genocide, but controversy still swirls around the term itself and its bearing on ethnic conflict elsewhere. The George W. Bush administration, perhaps influenced by its war on terrorism, described events in Sudan's Darfur region as genocide. Neither the African Union (AU) nor the European Union (EU) agreed. Across Sudan's regional divide, the North is better watered and mainly Arab. The South and West are arid and Christian or Animist. There, Janjaweed Arab militias supporting the Sudanese government are massacring farmers, presumed to support guerrillas of the Justice and Equality Movement (JEM) or the Sudanese Liberation Movement (SLM).

Long-standing ethnic conflicts, as in Rwanda, underlie Sudan's tragedy. Baqarra Arab nomads, prior to Janjaweed recruitment, clashed with Zaghawa, Fur, and Masalit farmers, and the region has long seen northerners enslave southerners. Genocide might accurately describe events in Darfur, where as many as 400,000 lives have been lost since 2003, but the history of supposed (Biafran) and actual (Rwandan) genocide forewarns us of ethnic and political complexities. In the Sudan, the way forward, as it should have been in Rwanda, is cautious support for the AU. Only in that way can mistakes made in Rwanda be avoided in the Sudan instead of being revisited on a scale approaching those that abetted Nazi atrocities.

Ethnic Cleansing in Europe—Yugoslavia

The campaigns of ethnic cleansing committed throughout the 1990s in the former Yugoslavian

federation, particularly in the province of Bosnia-Herzegovina at the hands of Bosnian Serbs and Serbian nationals, appalled a world community certain that the excesses committed during the Holocaust would never again plague Europe. The surge of nationalist sentiment unleashed by the end of the Cold War created the conditions that allowed this process, which ultimately led to the deaths of an estimated 200,000 Bosnian Muslims, Serbians, and Croats. The ambivalent behavior of international organizations, the United Nations (UN) and the North Atlantic Treaty Organization (NATO), in responding to policies of ethnic cleansing encouraged the actions of the Serbian perpetrators of genocide. The attempt at ethnic cleansing in the province of Kosovo several years later, in a Serbian attempt to cleanse the area of Kosovar Albanians, also triggered international outrage but resulted in an assertive military response by NATO led by the United States.

The conciliatory policies of Josip Broz Tito (1941–1980) maintained a fragile unity within the postwar multinational communist republic of Yugoslavia. Upon his death the devolutionist nationalist tendencies became unleashed, and his tactics of playing off the major ethnic groups against each other would not work any longer. In 1989 Serbian president Slobodan Milosevic (1989–2000) proceeded to eliminate the autonomous position of the Yugoslavian provinces of Kosovo and Vojvodina. His continued attempts to assert Serbian domination of Yugoslavia triggered the secession of Slovenia, Croatia, Macedonia, and Bosnia-Herzegovina in 1992. This angered Milosevic, triggering his deployment of the Yugoslavian military, composed primarily of Serbians, to reclaim the newly independent nations and unleashing a civil war. The attempts to create ethnically heterogeneous nation-states on the part of each former Yugoslavian republic, with the exception of Slovenia, resulted in various campaigns of ethnic cleansing in the midst of the Yugoslavian Civil War (1991–1998).

The ethnic cleansing policy on the part of various actors within Bosnia-Herzegovina was due to its multicultural character. The tenuous constitutional structure of newly independent Bosnia-Herzegovina rested on the supposed cooperation of its various component nationalities.

Bosnian Muslim women cry as their relative is buried in Potocari on July 11, 2005. Relatives wept over more than 600 coffins of victims of the Srebrenica Massacre, dug out of death pits at a ceremony to mark the 10th anniversary of Europe's worst atrocity in 50 years. (Damir Sagolj/Reuters/Corbis)

Unlike the other former Yugoslavian republics, it had no majority ethnic group but instead was composed of substantial pluralities of different nationalities. In 1991 a census estimated that Muslims accounted for 43.7 percent of the population, Serbians accounted for 31.4 percent, Croats accounted for 17.3 percent, Yugoslavs accounted for 5.5 percent, and others accounted for 2.1 percent.

The Serbian population, determined to maintain their political and cultural hegemony, proceeded to create the Republika Srpska under the leadership of Radovan Karadžić. The Bosnian Serb paramilitary formations, with covert assistance from Serbia, proceeded to ethnically cleanse Bosnia-Herzegovina of non-Serbs, primarily of Muslims. The age-old antagonism based on religious hatred emerged in the midst of the Bosnian Civil War. The resulting exterminations of Muslims with the associated tactics of widespread massacres, shootings, and mass rapes led to a massive death toll. Concentration camps and mass killings characterized the Bosnian Serb policies to exterminate the culture and populations of Bosnian Muslims. Armed groups of Bosnian Muslims retaliated by conducting their own campaigns of genocide against Bosnian Serbs.

➤ SREBRENICA MASSACRE—PORTRAIT OF A CONTEMPORARY WAR CRIME

The Srebrenica Massacre (July 1995) was the genocidal mass killing of approximately 7,000 Bosnian men in the region of Srebrenica in Bosnia-Herzegovina by nationalist Bosnian Serb Republika Srpska (VRS) units under General Ratko Mladić along with a mercenary Greek unit known as the Scorpions. This was the largest mass murder in Europe since the end of World War II and stands as an example of the controversy over the value of the United Nations (UN) peacekeeping mission amid the Serbian ethnic cleansing in Bosnia-Herzegovina.

The UN Security Council issued Resolution 819 on April 16, 1993, creating a UN Safe Area out of Srebrenica and its surroundings. This was meant to prevent the incursion of Bosnian Serb military actions against civilians. On April 18, the first contingents of United Nations Protection Force (UNPRFOR) troops arrived to serve as peacekeepers; these troops were mostly composed of Dutch units. By July, Serbian forces completely disregarded the UN decree and advanced into the region. The UN Dutch peacekeepers were unable to stop the VRS from murdering and raping the local populace, with some peacekeepers taken as hostages and, according to some reports, others turning a blind eye. Allegations of the UN Dutch battalion's negligence and incompetence surfaced in light of the killings. This massacre in addition to reports of UN forces' widespread corruption (selling arms, trafficking women) and sympathy with Bosnian Serbs made the UN strategy in Bosnia significantly controversial. The slow process of finding corpses in the Srebrenica region, often in mass graves, and of exhuming and identifying them lasted for a decade. Debate over the efficacy of peacekeeping operations in ceasing hostilities and preventing ethnic cleansing still plagues the UN.

Bibliography

Rohde, David. *Endgame: The Betrayal and Fall of Srebrenica, Europe's Worst Massacre since World War II*. Boulder, CO: Westview, 1998.

In the midst of the carnage, Serbia maintained official neutrality while supplying the Bosnian Serbs with arms and supplies.

Bosnian Croats and Muslims also enacted policies of attrition against the Serbs and each other in an attempt to eliminate each other from territories where a respective ethnic group constituted a demographic majority. Croatian forces concentrated their persecutions of Muslims in central Bosnia and most of Herzegovina. In the Bosnian town of Ahmici, Croatian militants perpetrated a massacre of Muslims by locking them in cellars and setting them afire. The smaller Muslim guerrilla force managed to commit small-scale massacres against both Croats and Serbs. A mass grave of potentially hundreds of Serbian civilians murdered by Muslim authorities that was unearthed near Sarajevo and abuses committed against Serbian prisoners at a Bosnian camp in Celibici are examples of Bosnian Muslim actions against their opponents. While Serbian genocide created a larger death toll, Croatian and Muslim actions also characterized the chaotic acts of ethnic cleansing on all sides.

The tactics involved in ethnic cleansing in the former Yugoslavia involved very crude methods of extermination and torture. Accounts of such actions involve shooting en masse, stabbing or knifing victims to death, torturing to death by various means, and starvation in concentration camps. The dehumanization of rival groups resulted in acts of mass rape, torture, and death. The participation of both paramilitary groups and civilians characterized many of these acts of genocide. Knowledge of these events troubled NATO and the UN in particular, which eventually sent in peacekeepers. Some accounts allege that there was inaction on the part of these forces that failed to prevent acts of genocide in some instances. Allegations of bribery and corruption of UN peacekeepers and their role as mere bystanders have also contributed to substantial controversy.

Following the Dayton Agreement in 1995, which brought an end to belligerency among the former Yugoslavian republics and settled differences in Bosnia, Milosevic proceeded to focus on affairs within Serbia. The province of Kosovo, which had a considerable Muslim Albanian popu-

lation, became the target of Serbian exclusionary legislation targeting non-Serbs. Kosovo Albanians were removed from universities and other venues of public life and encouraged to emigrate through government sanction. However, NATO and the UN were paying close attention to these actions on the part of Serbia. While Milosevic maintained that this was an internal affair and that he was merely responding to the actions of Muslim terrorist groups, NATO began a policy of aerial bombardment of key Serbian positions and the city of Belgrade in 1998 in retaliation for Serbian aggression against Kosovo.

U.S. president Bill Clinton enacted what political analysts refer to as the Clinton Doctrine, which advocates a policy of military engagement in nations with internal ethnic strife with the potential of escalating into genocide. This policy displeased Russia, which had backed Serbia's position in the Balkans as a sympathetic Slavic power. Diplomacy and the eventual granting of autonomy to Kosovo eventually diffused the issue. Milosevic was nonetheless proclaimed a war criminal and was seen as responsible for his involvement in actions in Bosnia-Herzegovina and his policy on Kosovo. He was eventually brought to trial in The Hague in 2000 for crimes against humanity, but he died on March 11, 2006, before the trial ended.

Nativist Revivals

Nativism can be defined as either loyalty to the ethnic, religious, or cultural group to which one belongs or as hostility to foreign influences such as immigrants and minority groups. Nativistic revivals are political movements of nations or peoples that coalesce around such sentiments. Nativism usually involves ethnic, racial, or religious prejudice. Nativism is wed to nationalism. Often nationalism can entail veneration of one's ethnic or religious culture rather than an affiliation with a larger nation-state. Since nationalism and nativism are bound together, there is often conflict among native residents of the nation and immigrants as well as between groups with conflicting nativist agendas.

Historically, nativism has been associated with the United States and the tendency of some Americans, including the Know-Nothing Party of the 1850s and the 1920s Ku Klux Klan, to blame all social problems on foreigners. Despite the term's association with American history, it can be applied to other countries because of the emphasis on the fear of the foreign. Ethnic conflicts in particular emerged as a feature of the post-World War II world, and after the end of the Cold War in the late 1980s there was an explosion of these conflicts. Nativist revivals occurred worldwide in the late twentieth century, including the Tamil-Sinhalese conflict in Sri Lanka, Chechnya's fight for independence from the Soviet Union, genocide in Bosnia and Rwanda, fighting between Muslims and Hindus in India, and anti-immigrant movements in the United States and Japan. Nativism, then, emerges as prejudices against outsiders, which causes conflict, political legislation, violence, and possibly genocide.

Since World War II, Yugoslavia was plagued with infighting between Serbs, Croats, and Muslims, and violence erupted in the 1990s that led to the Bosnian genocide (1992-1995) in which thousands of Bosnian Muslims were killed by Serb militaries. This ethnic cleansing was an attack on Muslims by Serbs, who identified their sense of nation with their religious background, Christianity. This nativist revival centered on the religious tolerance of Bosnia and particularly on

Bosnian Muslims. This genocide was a way to purify the nation of foreign religious influence.

Another example of religious differences leading to nativism is the Ayodhya conflict in India. In 1984, Hindu nationalists launched a campaign to reclaim the Ayodhya temple as a Hindu religious site. The controversy revolved around whether the Islamic mosque, built in 1528, was constructed on top of a Hindu temple to Rama. From the 1980s to the 1990s, riots occurred between Hindus and Muslims, resulting in the death of hundreds. For Hindu nationalists, this mosque became of a symbol of their majority threatened by the Muslim minority in India. In 1992, Hindu nationalists organized a rally at Ayodhya in which the mosque was destroyed. This destruction caused riots as well as attacks on Muslims. In Bombay, thousands of Muslims were killed.

Nativist revivals also occurred because of the departure of colonial powers, as in Africa. The removal of the colonial structure often caused tumult in countries such as Nigeria and Rwanda. In Rwanda, German and Belgian colonizers developed the system of identifying Hutus and Tutsis, and Tutsis were given better jobs and education than Hutus. By the 1990s, the two groups had intermarried to the extent that their ethnic differences were indistinguishable, yet the preferential treatment due to ethnicity caused animosity. In 1994, the genocide began with the death of the Rwandan president, which was blamed on the Tutsis. Hutus killed over 1.5 million Tutsis, and Tutsis rebels responded by killing over 100,000 Hutus.

Nativism also emerges in less violent and more political forms. For example, in 1979, the

Iranian Revolution displaced the shah and reinstated Islamic law in the country. This revolution favored the laws of Islam to the Westernization of the country, which was seen as foreign and corrupting. In the United States, there is a long history of identifying immigrants as threats to the national character. In contemporary America, nativist revivals have taken the form of protests and legislation against immigrants; following the September 11, 2001, attacks on the World Trade Center, such nativism has gained popularity and brought about new federal initiatives concerning border regulations and immigrants' rights on American soil. Nativist revivals thus have emerged in full force in the contemporary world as reaction to perceived threats to nation, culture, and personal identity.

■ Introduction: Terrorism

Terrorism is the systematic use of violence by domestic or international organizations for specific political objectives. While the use of terrorism is not a new development in world history, it has become more prevalent since 1945. Factors for its growth include the postwar acceleration of decolonization, separat-

ist movements and their struggle for national liberation, and growing Islamist resentment against U.S. hegemony and the more amorphous forces of globalization.

Types of terrorism include state terrorism, domestic terrorism, and nonstate actor terrorism. State terrorism involves use of coercion through

violence on the part of a police state to eliminate dissent and cow the population into ideological submission (e.g., Argentina, China, and South Africa). Domestic terrorism involves the use of violence against civilians or public officials to promote a political cause by a clandestine organization bent on the overthrow of the state or to promote a national separatist move-

ment (e.g., Irish Republican Army in Northern Ireland, Red Army Faction in Germany, and Aum Shinrikyo in Japan). Nonstate actor terrorism is directed against what is perceived as foreign occupation by a foreign state by international terror organizations utilizing asymmetrical warfare against civilian populations and military forces (e.g., al-Qaeda's September 11, 2001, attacks in

➤ MAJOR TERRORIST ATTACKS TIMELINE

- July 22, 1946—The Zionist militant group Irgun bombs British military headquarters at the King David Hotel in Jerusalem, killing 91 people.
- September 15, 1963—The Ku Klux Klan bombs a church in Birmingham, Alabama, killing four African American girls.
- July 21, 1972—Known as Bloody Friday, the Provisional Irish Republican Army bombs Belfast, Northern Ireland, killing 9 people and injuring 130.
- September 5, 1972—The Palestinian terrorist group Black September kidnaps 11 members of the Israeli Olympic team from the Olympic village in Munich, Germany. All 11 athletes die.
- October 6, 1976—Anti-Castro Cuban exiles, with alleged ties to the Central Intelligence Agency (CIA), bomb Cubana Flight 455 en route to Havana, Cuba, killing all 73 passengers and crew.
- 1978–1995—Theodore Kaczynski, an American terrorist better known as the Unabomber, kills 3 people and injures 29 in a string of antitechnology letter bombings.
- August 2, 1980—The far-right Italian group Ordine Nuovo bombs the railway station in Bologna, Italy, killing 85 people and wounding more than 200.
- October 23, 1983—Two suicide truck bomb attacks by Islamic jihad kill 241 U.S. servicemen and 58 French paratroopers in their barracks in Beirut.
- March 8, 1985—A car bomb, allegedly planted by the CIA, explodes in Beirut, Lebanon, near the home of prominent Islamic cleric Sayyed Mohammad Hussein Fadlallah, killing 80 people and injuring 175.
- June 22, 1985—Unknown terrorists bomb Air India Flight 182 in flight from Canada to India, killing all 329 passengers and crew.
- April 21, 1987—Tamil Tigers bomb a bus terminal in Colombo, Sri Lanka, killing 110 people.
- December 21, 1988—A Libyan agent plants a bomb on Pan Am Flight 103, which explodes over Lockerbie, Scotland, killing all 270 passengers and crew.
- April 19, 1995—American terrorist Timothy McVeigh bombs an office complex in downtown Oklahoma City, Oklahoma, killing 168 people.
- August 7, 1998—Arab terrorist network al-Qaeda bombs U.S. embassies in Tanzania and Kenya, killing 225 people and injuring over 4,000.
- October 18, 1998—The Colombian rebel group National Liberation Army (ELN) bombs a pipeline near Machuca, Colombia, resulting in fires that kill 84 people and injure 100.
- September 11, 2001—Al-Qaeda operatives hijack four airliners, crashing two into the World Trade Center in New York City; one into the Pentagon in Arlington, Virginia; and one into a field in Pennsylvania. In all, 2,997 people are killed.
- October 23, 2002—Chechen terrorists take 850 hostages in a Moscow theater. Russian police mount a botched rescue attempt three days later, and 120 hostages and 40 terrorists are killed.
- March 11, 2004—Al-Qaeda operatives bomb commuter trains in Madrid, Spain, killing 191 people and injuring over 1,500.
- July 7, 2005—Al-Qaeda-linked terrorists explode four bombs in London, killing 52 people and injuring over 700.
- July 11, 2006—Islamic militants carry out a series of bombings on commuter trains in Mumbai, India, killing 209 and injuring 700.
- November 26–29, 2008—In Mumbai, India, nearly 200 people are killed when 10 gunmen armed with bombs and grenades attack a train station, a cafe, luxury hotels, a Jewish cultural center, and a hospital during a three-day rampage.

—Logan Craig

the United States and Jemaah Islamiyah's Bali bombings in Indonesia that killed mostly Australian civilians in 2002).

Methods utilized by terrorists include bombings of public infrastructure in urban areas (e.g., the London bombings of July 7, 2005, and the Madrid bombings of March 11, 2004, both by al-Qaeda cells), suicide bombing attacks on civilian populations (e.g., Israel, Iraq, and Afghanistan), or the use of asymmetrical warfare by nonstate actor militias against state military forces and civilian institutions (e.g., Iraq, Afghanistan, and Northern Ireland).

The word "terrorism" is an ideologically laden term, as it implies a senseless application of violence and an absolute rejection of the perpetrators' objectives. Yet most societies and peoples tend to sanction some uses of violence, such as state executions or militaries aimed, purportedly, at national defense. Particularly since the 9/11 attacks on the United States, the word "terrorism" has become something of a catchall in public discourse in the West to condemn any and all use of violence with political intent, leading to the rise of such terms as "ecoterrorism" to describe radical environmentalists' attacks on property and "cyberterrorism" to describe the hacking of sensitive Web sites.

—*Abraham O. Mendoza*

State Terrorism

The term "state terrorism" is used to describe any instance in which a state systematically directs and advocates violence against the civilian population of its own or that of another state through military or clandestine actions. It is a form of terrorism in that it seeks to destroy the stability of the day-to-day livelihood of a group of people in order to coerce or to change an existing social or political structure. Such actions include the use of covert operations through domestic police, military, and intelligence agencies; covert operations through subsidized foreign organizations (freedom fighters); and acts of war directed at the civilian population by both legitimate and clandestine military actors during internationally sanctioned warfare. State terrorism is different from war in that it is directed against the civilian population as a means to weaken

and overthrow an enemy government, nonstate actors, or covert organizations. Such actions disregard statutes of international law, most notably the 1949 Geneva Convention Relative to the Protection of Civilian Persons in Time of War.

State terrorism is characterized by the systematic destruction of civilian elements that are deemed to be a potential threat to the aggressor government. These might be within the country itself or an enemy nation. Well-documented cases of domestic state terrorism include the Argentine Dirty War (1976–1983), Salvador Allende's repressive regime in Chile (1973–1990), and endemic human rights abuses in the Eastern Bloc (e.g., the German Democratic Republic, Romania, Hungary, Czechoslovakia, and the Soviet Union) throughout the postwar period to the fall of communism (1945–1991). In the Eastern Bloc instances, the government through internal police, military, and intelligence services, working in tandem with elements in the general civilian population, removed from public life civilians deemed a threat to the existing state. These removals were characterized by internal espionage, mass arrests (sometimes in secret to avoid public scrutiny), torture, show trials, and summary executions. The Serbian ethnic cleansing campaigns in Bosnia-Herzegovina (1991–1995) and Kosovo (1995–1999) are examples of both domestic and foreign state terrorism on behalf of the Serbian government. The genocidal policy in the Darfur region of Sudan is a current example of a government taking it upon itself to destroy segments of its own civilian population for state purposes.

State terrorism also involves the actions of one state directing violence toward the civilian population of another state through a legitimate war sanctioned by international law. In this case, a particular state threatened by another state directly or indirectly by military aggression decides to respond with its own military force in ways that inevitably target civilian populations. The concept of total war partially legitimized during World War II, which deems the destruction of civilian institutions as legitimate military targets given that without these the aggressor state would be unable to continue the struggle, creates optimum conditions for legitimizing state terrorism. Under this logic, to destroy the state

one must destroy the stability that the state ensures for its citizenry, resulting in the eventual overthrow or reversal of the state or its policies.

Recent examples of alleged state terrorism under the pretext of war include National Socialist Germany's domestic atrocities and bombing of Allied cities (1939–1945), British and American bombardment of German cities (1940–1945), the American atomic bombing of the Japanese cities of Hiroshima and Nagasaki (1945), the American actions against civilians in the Korean War (1950–1953) and the Vietnam War (1961–1975), the French repression in Algeria (1954), and Israeli air strikes and military offensives in its wars against its Arab neighbors (1948, 1956, 1967, 1973, 1981). State-sponsored attacks by Iran and Saudi Arabia through proxy terrorist organizations on the State of Israel are also egregious examples of state terror. Some scholars suggest that the current U.S.-British war in Iraq (2003–present) is an example of state terrorism.

Violence against civilians in these wars is characterized by the widespread destruction of life and property, myriad human rights abuses, and massive collateral damage of innocent bystanders during the aerial bombardment and artillery attacks of enemy cities. Public support of such total war tactics has been crucial to the undertaking of such wars, given that these bombing campaigns might prevent or forestall costly military invasions both financially and in terms of casualties.

State terrorism outside of the conduct of war is also enacted indirectly by one state against another through the use of its intelligence services operating in secret, subsidizing and operating with foreign nonstate actors, and through the overthrow and/or support of regimes deemed to be necessary for domestic national security rationale. Intelligence organizations such as the U.S. Central Intelligence Agency (CIA), the Soviet KGB (Committee of State Security), and the Israeli Mossad have actively operated on foreign soil in their efforts to dismantle, disrupt, and destroy foreign governments seen as a threat to their national security. Political assassinations, destruction of life and property, and collateral damage to civilians have been part of the policies of such intelligence services in carrying out their actions.

—Abraham O. Mendoza

➤ THE ARGENTINE DIRTY WAR AND THE *DESAPARECIDOS*

The Argentine Dirty War (1976–1983) resulted in widespread human rights violations characterized by the torture, arrest, and execution of leftist political dissidents by the right-wing military dictatorship of General Jorge Rafael Videla. The Argentinean armed forces, under the leadership of a rightist military clique, overthrew the existing government on March 24, 1976. The military junta that seized power subsequently enacted a campaign to liquidate Argentina of potential dissidents. Scholars, intellectuals, university students, and politicians associated with the previous liberal regime were removed from public life, never to be seen again (*desaparecidos*), by state police personnel operating clandestinely. The authoritarian regime saw any potential dissent as a threat to their hold on power and enacted censorship legislation, curtailed civil rights, and continued to remove from society people deemed to be threats.

The arrests, torture, and execution of the *desaparecidos* (the disappeared ones) indicate massive human rights violations that resulted in an estimated 6,000 to 15,000 deaths from 1975 to 1981. International outrage resulted in growing pressure against the Argentinean government, including decreased economic aid and diplomatic pressure. In 1983 greater compliance with international opinion resulted in the relaxation of the worst abuses and the installation of a democratically elected regime. Subsequently, General Roberto Eduardo Viola and General Leopoldo Galtieri, the generals who had led the military coup, were tried and imprisoned.

SHINING PATH

Shining Path (Sendero Luminoso) is a violent Marxist revolutionary group in Peru. Its founder, Abimael Guzman, was a professor of philosophy who had studied Maoism in China. Shining Path was not an organization born of peasant or worker beginnings but rather one that sprung out of a radical student organization.

Guzman started his violent revolutionary movement in 1980. His initial goal was to stop democratic reform in Peru, and his initial targets were polling places and newly elected officials. In the 1980s and 1990s Shining Path participated in a wave of bombings that would include everything from government buildings to churches. Shining Path used terror, including a campaign of killing police officers, as a part of its platform for change. By the mid-1980s Shining Path had made alliances with drug traffickers to fund its revolution.

Ultimately, Guzman was arrested and sentenced to life in prison in 1992 by the administration of Alberto Fujimori. In 2003 the Peruvian government, in a rebuke of Fujimori's autocratic tactics, declared Guzman's trial void. This declaration also applied to approximately 2,000 Shining Path members. Guzman, however, was convicted again in 2006 and sentenced to life in prison. While Shining Path never successfully brought about its mission of revolution, the teachings of Guzman continue to be influential to Marxist revolutionaries, some of whom are again operating in the Amazon jungles of eastern Peru.

—Richards P. Davis

Islamic Radical Terrorism

In the late twentieth and early twenty-first centuries, radical Islamic terrorism emerged as a global phenomenon. Islamic terrorists perpetrated attacks in Europe, North America, the Middle East, Africa, and South and Southeast Asia.

There is no singular reason why people, including Muslims, carry out terrorist attacks. Scholars also cannot pinpoint the birth of the Islamic terrorist movement, since that would imply a unity within the Islamic world that does not exist. While Islam is the majority religion in more than 60 nations and a minority religion in more than 100 more, it is divided up into many

sects, Sunnis and Shia being the two most prominent. The modern world has seen both Sunni (al-Qaeda, Hamas), and Shia (Hizbullah) forms of terrorism. Although several of these Sunni and Shia groups have worked together over the years, in many instances radical Sunni and Shia groups consider each other to be even greater threats than non-Muslim groups. This is because many Muslims believe that before they can attack outsiders, they must cleanse the lands of Islam of impious Muslims, who to many radical Sunnis are Shia and vice versa.

Although many citizens in Europe and North America have long associated with the Middle East and thus Muslims, the vast majority of terrorist acts carried out by Middle Easterners prior to the mid-1980s were inspired by secular, often Marxist-Leninist or nationalistic ideas. In fact, many Arab Muslim leaders associated with either state- or guerrilla-sponsored terrorism including Yasser Arafat (Palestinian), Saddam Hussein (Iraq), Mohammar Qaddafi (Libya), and Hafez al-Asad (Syria) were secular leaders who often feared Islamic movements.

The reasons behind the rise of Islamic terrorism are not entirely clear, but most scholars point to the perceived failure of the secular Western model of development, internal resentment toward the repressive regimes throughout much of the Islamic world, the West's support of Israel at the expense of the Palestinian refugees, and high rates of unemployment in many Islamic nations. Furthermore, many Muslims have grown increasingly upset over their secular governments' inability to oppose foreign interference in their nations' domestic and foreign affairs.

Such discontent has also spilled into Muslim immigrant populations. Over the past decade many European nations have also witnessed the rise of homegrown Islamic terrorism among second- and third-generation Muslims residing in these countries. An example of this was the attacks on London on July 7, 2005, in which a group of homegrown British terrorists attacked domestic targets.

While many modern Islamic movements, including terrorist groups, boast that they want to unify the Islamic world as it had been under Muhammad and the subsequent Four Rightly Guided Caliphs (ca. 622–660 CE), it is a mistake

to view these movements as inherently anti-modern. These groups often employ modern communications technology and innovative interpretations of the Quran and other sacred Islamic writings and, perhaps most importantly, are reacting against the perceived inequalities of the modern nation-state system. Therefore, although many of these groups proclaim their desire to return to a Golden Age of Islam, they are using modern means to recruit new members and to organize and carry out attacks.

During the late nineteenth and early twentieth centuries, Islamic reformers such as Mohammed Abduh in Egypt and Jamal al-Din al-Afghani in the Persian Gulf region attempted to harmonize traditional Islamic life with the modern world. Although important, these were but two of the first in a series of Islamic reformers over the course of the late nineteenth and twentieth centuries. By 1928 during the British occupation of Egypt, Hassan al-Banna founded the Muslim Brotherhood, an Islamic political organization dedicated to the eventual founding of a single supra-Islamic state. While many members of this new organization took part in sporadic acts of violence against the British and later Israelis in Palestine between 1936 and 1949, most notably during the Palestinian uprising against the British (1936–1939), this group remained primarily dedicated to a policy of nonviolent reform. The Muslim Brotherhood, like many later Islamic political movements, eventually came into conflict with Egypt's secular leadership and, under Gamal Abdel Nasser's rule in the 1950s, was banned from public life.

In the post-World War II era, perhaps the most influential Islamic reformer, at least to Sunni Muslim terrorist groups, was Sayyid Qutb, an Egyptian member of the Muslim Brotherhood who was imprisoned during Nasser's reign. During one of his periods of incarceration at the hands of Egyptian authorities, Qutb wrote *Signposts*, his contribution to Islamic political thought. In this work Qutb argued that before jihad could be successfully waged against Islam's enemies, Muslims would first have to cleanse their lands of Islamic impostors. These came to include secular Muslim leaders.

The 1970s were a decade of silent growth for many Islamic movements, but following Ayatollah

Khomeini's successful revolution against the Reza Shah Pahlavi in Iran in 1979, radical Islam burst onto the international scene. Although Khomeini's was a Shia revolution and rather hostile to other forms of Islam, his movement's success encouraged both Sunni and Shia groups throughout the Islamic world. Around the same time as Iran's revolution, the Soviet Union invaded Afghanistan to prop up a pro-Soviet government, and this infuriated much of the Islamic world. Following the Soviet invasion, thousands of Sunni Arab Muslims from Gulf nations such as Saudi Arabia and Mediterranean nations such as Egypt descended upon Afghanistan to wage jihad (holy war) against the so-called godless communist invaders. There is currently a debate under way within academia over the U.S. role in aiding these anti-Soviet fighters, but it is clear that the United States provided both military and economic aid to the Afghan resistance.

By the late 1980s many new groups had formed. These included Hizbullah, a Shia group forged in the middle of the Lebanese Civil War to fight both Lebanese Christians and Israeli soldiers, and Hamas, a Sunni Palestinian offshoot of the Muslim Brotherhood established during the First Intifada in 1987 to fight Israel. Following the Soviet withdrawal from Afghanistan and the subsequent American invasion of Iraq, many Islamic terrorist groups switched their focus from the Soviet Union to the United States. The most prominent of these movements was al-Qaeda, led by Osama bin Laden, a wealthy Saudi expatriate who had fought in Afghanistan. In the late 1990s bin Laden's group merged with Ayman al-Zawahiri's Egyptian Islamic Jihad to form what would become the most notorious terrorist group of the early twenty-first century. Al-Qaeda has claimed responsibility for several major attacks on U.S. and West European targets, most notably the September 11, 2001, attacks in New York City and Washington D.C.; the March 11, 2004, attacks in Madrid, Spain; and the July 7, 2005, subway and bus bombings in London, England.

While al-Qaeda has become the most well-known Islamic terrorist group, other groups have continued to attack targets around the world. Since 1994 the Chechen independence campaign has led to warfare in this majority-Muslim territory as well as Chechen terror attacks inside

Russia. Southeast Asia is home to Jamaat Islamiyya, a Sunni Indonesian-based group best known for the 2002 bombing of a nightclub in Bali that led to the deaths of more than 200 civilians, mostly Australians. Between 1994 and 2001 Afghanistan was ruled by the Taliban (Sunni), an ultra-religious group that aided and sheltered bin Laden and his al-Qaeda network until the United States and a coalition of Afghani warlords removed them from power. Between 2001 and 2006 the Pakistani Shia community suffered through a series of attacks at the hands of radical Sunni groups. Egypt, Saudi Arabia, and Jordan have also endured major attacks on their civilian populations and Western targets in their countries. Finally, the Israeli-Palestinian conflict continues unabated, fueling Islamist attacks on Israeli civilians.

In the 1990s several prominent scholars argued that radical Islamic politics, although increasingly violent, had reached its zenith and would soon begin to gradually lose popular support throughout the Islamic world. While it may be too soon to totally reject this hypothesis, it is evident in the early twenty-first century that Islamic terrorism will continue throughout the foreseeable future.

Hizbullah

Hizbullah, the Party of God, is a Shia Lebanese political party that was founded in the wake of Israel's 1982 invasion of Lebanon. Some, both in Lebanon and abroad, consider Hizbullah a ter-

rorist organization, while others view Hizbullah as a legitimate political party. In fact, Hizbullah has both a political and a military wing. The political wing engages in all levels of Lebanese politics, where it enjoys immense support from Lebanon's Shia community and even certain segments of the Christian population. The military wing of Hizbullah occasionally clashes with the Israeli military and has been accused of perpetrating terrorist acts against American, Israeli, and Jewish targets.

Hizbullah's founding and rapid rise to prominence in Lebanon in the early 1980s signaled the arrival of Lebanon's Shia population on the national scene. Although they had long been the largest single religious group in Lebanon, earlier French policies, which were translated into official Lebanese policies following independence, promoted Christian and Sunni but not Shia interests.

While Hizbullah is a Lebanese movement, it has been greatly influenced by Shia in other parts of the Middle East. In the 1960s and 1970s many of Hizbullah's leaders studied in Iraqi religious schools, where they came into contact with Iranian and Iraqi thinkers, most notably Ayatollah Khomeini of Iran. Furthermore, following Israel's invasion of Lebanon in 1982, Khomeini's government in Iran sent members of his military to Lebanon to aid the Shia. These soldiers helped spread revolutionary Shia ideology among the Lebanese Shia.

Initially Hizbullah was engaged in military activities against Israel and its Christian Phalange allies, who had perpetrated massacres at the Palestinian refugee camps of Sabra and Shatila. Although Hizbullah is a Shia resistance group, its leadership also draws a good deal of prestige from its support of Palestinian national and Islamic movements. Hizbullah is also believed to have perpetrated the deadly suicide attack on the U.S. Marine barracks in Beirut in October 1983 that left 243 American soldiers dead and to have kidnapped tens of foreign nationals. In the 1990s Hizbullah was also implicated in deadly attacks on a Jewish youth center in Buenos Aires, Argentina, and an attack on the Israeli embassy in Argentina.

From 1982 to 2000 Hizbullah's military wing spent most of its time engaged with the Israeli

military and Israel's ally, the Southern Lebanese Army, which occupied much of southern Lebanon. In 2000 Israel unconditionally withdrew its forces from southern Lebanon. This withdrawal was viewed throughout the region as a Hizbullah defeat of Israel, boosting the group's prestige. Hizbullah continued to maintain that Israel was still occupying the Shebaa Farms on the Lebanese-Syrian border, which many international actors actually claim belongs to Syria.

In July 2006 Hizbullah kidnapped two Israeli soldiers and killed three others, leading to a 34-day conflict. Hizbullah claims that the Israelis were captured on Lebanese soil, while Israel claims that Hizbullah militants illegally crossed into Israel. In the conflict that followed, the Israeli Air Force and Army wrought destruction on southern Lebanon and Beirut while Hizbullah launched rockets into northern Israel, creating a sense of mass panic in Israeli cities. Following the war, which ended as a standoff although both sides sought to claim victory, both Israel and Lebanon suffered through political crises. Although the vast majority of Lebanon's population eventually came to support Hizbullah's fight against Israel, many Sunnis and Christians resented being dragged into the middle of Hizbullah's war. This led to demonstrations by Hizbullah against the government and counterdemonstrations by progovernment forces against Hizbullah. In Israel, Prime Minister Ehud Olmert's popularity fell to just over three percent in the months following the war.

Over the past quarter century Hizbullah has grown from a resistance movement into a full-fledged political-military organization. As of 2009 it is one of the two largest political parties in Lebanon. Yet it is considered a terrorist organization by many Western nations including the United States. Still Hizbullah remains highly popular among Lebanese Shia and enjoys popularity among other segments of Lebanon's population as well.

➤ SHEBAA FARMS

Between the border of Lebanon and the Golan Heights is the tiny Shebaa Farms, which has been disputed among Israel, Syria, and Lebanon. The total area measures between approximately 5.5 miles (8.6 kilometers) in length and an estimated 1.5 miles (2.4 kilometers) in width. As a point of contention among the three states, in spite of the small size of Shebaa Farms, scholars and policy makers on all sides point to Ottoman surveys and French Mandate maps to illustrate who has the most legitimate claim to its possession. Hizbullah and Lebanese officials view the area as an integral part of their state, taken by force by Israel. While Syria currently views Shebaa Farms as part of its state, it has argued in the past that it is part of Lebanon. Syrian influence over Lebanese affairs in the past has made its relations with that state contentious. Israel viewed the tract as having been Syrian and never Lebanese when it was seized during the Six-Day War (1967) by Israeli forces. The United Nations (UN), which effectively ordered the Israeli withdrawal through UN Resolution 425 in 1978 (a withdrawal that has not yet occurred), is unclear as to who has title to this land, also basing its ruling on vague maps from prior disputes between Syria and Lebanon. Continued Israeli possession of the region in addition to the greater conflict over Palestine continue to sour relations among the three states.

—Abraham O. Mendoza

The Muslim Brotherhood

The Muslim Brotherhood was founded in Egypt by Hassan al-Banna in 1928. Al-Banna hoped to peacefully transform Egypt into an Islamic nation that would uphold Islamic Sharia law and become free of foreign interference. The Muslim Brotherhood was influenced by older thinkers such as Jamal al-Afghani and Muhammad Abduh, himself Egyptian, who published works praising the merits of Islamic government, though neither Abduh nor al-Afghani fully rejected Western ideas.

Throughout the 1930s and 1940s the Muslim Brotherhood, which was more of a spiritual organization than a political party, slowly spread through the Arab Middle East, most notably in

Palestine, Transjordan, and Syria. While some Muslim Brotherhood activists adhered to a peaceful worldview, others adopted violent practices, especially in Palestine where members of the Muslim Brotherhood took part in the Palestinian Revolt during 1936–1939. The Muslim Brotherhood gained popularity through charitable acts, resisting Zionism, and appealing to Middle Eastern Muslims' Islamic background. In Egypt the ruling class began to fear the Muslim Brotherhood's rising power. Following the assassination of the Egyptian prime minister in 1948, Egyptian authorities claimed that the Brotherhood was responsible and murdered al-Banna.

Although they had helped the Free Officers Revolution in Egypt in 1952, the Officers, led by Muhammed Naguib and Gamal Abdel Nasser, cracked down on the Brotherhood during the 1950s, arresting scores of activists. One such activist was Sayyid Qutb, an ideologue who was executed in 1967 after years in prison but who wrote an influential book while incarcerated. This book, often translated as either *Signposts* or *Milestones*, justified the murder of rulers of Middle Eastern countries if those rulers did not ascribe to proper Islamic ways. Quttub compared these rulers to those who had dominated Arab lands prior to the rise of Islam (the Jahilliya period) and argued that they lacked legitimacy. His work influenced later Islamist thinkers including Osama bin Laden.

The Muslim Brotherhood also ran afoul of the secularist Syrian Baathist party two decades later. In 1982, fearing that members of the Muslim Brotherhood in Syria were a threat, Syria's leader Hafez al-Asad launched a devastating attack on the city of Hama, killing not only Brotherhood activists but tens of thousands of innocent civilians. Other crackdowns, though none involving even close to this amount of violence, occurred in Egypt during the 1990s and the early twenty-first century.

Today the Muslim Brotherhood's power can be felt in numerous countries. In Egypt, the Brotherhood is the leading opposition group to Hosni Mubarak; in Jordan, the Brotherhood would most likely seize power if open elections were held; and in the Palestinian territories, Hamas, a Brotherhood spin-off, rules Gaza, while the Palestinian Islamic Jihad, an even more mili-

tant spin-off of the Brotherhood, continues to launch attacks against Israeli civilians. The common theme that connects the various Muslim Brotherhood sects is an opposition to secular rule in the Middle East. Thus, while they remain feared by Westerners, the Muslim Brotherhood groups pose a far larger threat to secular Arab leaders in the region and therefore continue to be persecuted by secularist regimes.

The Palestine Liberation Organization

The Palestine Liberation Organization (PLO) was founded in 1964 by Palestinian representatives from both the West Bank and Gaza and the Palestinian diaspora with the support of the Arab League. The idea of a Palestinian national body was Egyptian leader Gamal Abdel Nasser's. Nasser, constantly concerned with Israeli military power and his own peoples' unfulfilled political-economic desires, championed the new organization that would demonstrate to the Arab world and to Nasser's domestic constituency that he was doing something constructive for the Palestinians while effectively shifting the burden of representation to the new body. The existence of the PLO would place even greater military pressure on Israel, Egypt's most powerful and feared enemy. Initially the PLO, which was headed by Ahmed al-Shuqayri, was a weak organization that was under the military control of the countries in which it operated (Egypt, Syria, and Jordan). Following Israel's lightning victories over Egypt, Syria, and Jordan in 1967 and its subsequent military occupation of Gaza and the West Bank, which brought the majority of Palestinians under Israeli control, Yasser Arafat was able to take control of the PLO. Arafat, an Egyptian-educated Palestinian who had fought in the 1948 war, aimed to liberate all of Mandate Palestine, including the 78 percent that had become the State of Israel, in order to create a secular Palestinian state. He had previously founded Fatah, a secular

➤ HAMAS

Hamas is an offshoot of the Muslim Brotherhood movement that was founded in Egypt in 1928 by Hassan al-Banna. Hamas emerged as an independent entity during the early stages of the first Palestinian Intifada (1987–1993) under the leadership of Shekh Ahmed Yassin (ca. 1936–2004). Although most members of the Muslim Brotherhood in the Palestinian territories in the 1970s and early 1980s hoped to use nonviolent means to gradually transform Israel, the West Bank, and Gaza into one Islamic state, by the late 1980s the new Hamas movement had adopted violence as their chief tactic.

Unlike Fatah, the secular military wing of the Palestine Liberation Organization (PLO), Hamas in this period was not part of the overall Palestinian government. Thus, Hamas reacted angrily to the PLO's tacit acceptance of Israel in the late 1980s and to Yasser Arafat's formal signing of the Oslo Accords in 1993. Following these events, through suicide bombings in heavily populated civilian areas in Israel, Hamas attempted to derail the peace process in the mid to late 1990s. In this period Hamas was not just a military-resistance organization but also provided much-needed educational, social, and medical services to Palestinians. Compared to the notoriously corrupt PLO, which remained in control of the Palestinian Authority (PA) following the 1993 Oslo Accords, Hamas was able to present itself to its constituents as a charitable and honest party.

The Israeli Army assassinated Hamas founder Sheikh Yassin in March 2004 and his successor Dr. Abdel Aziz Rantisi a month later. Hamas has also faced opposition, occasionally armed, from Palestinian groups. Their fiercest competition has come from Arafat's Fatah faction, which aims to create a secular Palestinian state based on socialist-inspired values. On the Islamic side they have also come into conflict with Palestinian Islamic Jihad, another violent offshoot of the

Muslim Brotherhood. Palestinian Islamic Jihad has been, if anything, more violent than Hamas and has often accepted aid from Iran and Hizbullah. Still, Palestinian Islamic Jihad, perhaps because of its refusal to moderate its positions, has failed to match Hamas's steady rise in popularity over the past 20 years.

During the Second Intifada (2000–present) Hamas has continued to simultaneously attack Israeli military and civilian targets while providing desperately needed domestic services to its constituents. Thus, the new round of violence proved to be a boon for the organization. In 2005 Hamas delegates won over 50 percent of the popular vote in Palestinian legislative elections, bringing their group into power for the first time. Upon entering office the new Hamas-led government quickly came into conflict with the United States over its refusal to honor previous Palestinian agreements to recognize Israel's right to exist. Furthermore, since the democratically elected president of the PA remains Mahmoud Abbas, Arafat's successor, Hamas has not been able to implement many of its policies. It is unknown whether Hamas will follow other Islamic movements in moderating its positions now that it has come to power or if it will continue to pursue violent tactics against enemy civilians as one of its major policies. Recent evidence, including Hamas's decision to abide by a truce with Israel (February 2005–present), indicates that Hamas has the potential to become a moderate party.

group that was nevertheless influenced by the Muslim Brotherhood, in order to conduct raids against Israeli targets and to help build a Palestinian military force. His fellow Fatah commanders also came to dominate the PLO's leadership following the 1967 war.

By the early 1970s, the PLO had established a state within a state in Jordan, which was home to a sizable Palestinian minority. Worried that Palestinian military activities were undermining his nation's sovereignty, Jordan's King Hussein attacked the PLO in September 1970. Although

the conflict threatened to escalate into a regional war, Jordan was eventually successful and drove the PLO leadership out of Jordan and into Beirut. Following this event, however, the PLO leadership soon rebounded, and by the mid-1970s the PLO had established itself as the global representative of the Palestinian people.

During their stay in Lebanon the PLO leadership again established a state within a state and continued to launch raids against Israel. In 1982 Israel invaded Lebanon in an attempt to drive the PLO out of Beirut. Although this invasion had disastrous public relations and political ramifications for Israel, by late 1982 the PLO leadership had agreed to leave Lebanon, with the United States guaranteeing their safe passage. The PLO leadership soon relocated to Tunisia.

In the late 1980s two key events helped transform the PLO: the first Palestinian Intifada (uprising) and the U.S.-PLO dialogue. The intifada against Israel's 20-year occupation began in Gaza and soon spread to the West Bank, bringing international attention to the Palestinian cause. At the same time the PLO leadership announced its intention to honor previous United Nations resolutions that called for a two-state solution to the Israeli-Palestinian conflict. Following this announcement, U.S. president Ronald Reagan's administration entered into its first official dialogue with the PLO. Although short-lived because of Arafat's subsequent support of Saddam Hussein in the 1991 Gulf War, this marked the beginning of the U.S.-PLO dialogue.

By the early 1990s the Israeli government and the PLO had entered into secret negotiations in Oslo, Norway, regarding a future peace settlement. In 1993 Arafat and Israeli prime minister Yitzhak Rabin signed the Oslo Accords at the White House, thus ushering in a new era of Israeli-Palestinian relations. Unfortunately, Rabin came under significant attack by right-wing politicians in Israel such as Ariel Sharon and Benjamin Netanyahu, while Arafat was challenged by a new Palestinian Islamist movement, Hamas, that rejected the idea of a two-state solution and aimed to establish an Islamic government in all of Mandate Palestine. The situation continued to deteriorate. In 1995 Rabin was assassinated by a Jewish militant, and during the mid- to late 1990s Hamas unleashed a series of suicide bomb-

ings inside Israel. Meanwhile, Israel continued to build settlements in the West Bank and Gaza, and the PLO leadership was accused of large-scale corruption by Palestinians and foreigners. By 2000 the Oslo Accords had proven to be a failure, as Arafat and then Israeli prime minister Ehud Barak could not come to a final agreement over a future peace.

In 2000 a new, more violent intifada broke out in the West Bank and Gaza that included suicide attacks against Israeli civilians. Israel responded by using collective punishment against Palestinian militants and civilians. In 2005 Arafat died, and the Palestinians held a new election, voting Hamas into office and thus ending Fatah's (in reality the PLO's) 38-year rule. In 2007 a civil war erupted in Gaza in which Hamas drove Fatah supporters from the area. Fatah responded by taking control of the West Bank with international support. Thus, as of 2009 not only are the Palestinians without their own state, but they also lack any semblance of national unity.

U.S. Domestic Terrorism

Events such as the September 11 attacks in 2001 and the first bombing of the World Trade Center in 1993 demonstrate that the threat of terrorism within the borders of the United States is considerable. In fact, the United States has suffered a number of terrorist attacks in its history, with terrorism broadly defined as attacks against civilian targets for political or ideological purposes. The perpetrators have often been American citizens. Underground radical groups such as the Weathermen orchestrated bombing campaigns in the 1960s and 1970s. The Oklahoma City bombing of 1995, the Unabomber series of mail

► ECOTERRORISM

The term “ecoterrorism,” coined only in recent decades, is used to describe acts and threats of violence against people or property, sabotage, vandalism, and intimidation committed in the name of environmentalism by political activists. The attacks are often of a symbolic nature; for instance, ecoterrorists will vandalize a logging site or a luxury car dealership or commit arson against a new home development believed to threaten a local ecosystem. There have been well over 1,000 separate incidents of ecoterror in recent decades. While there have been no known human deaths as a result of ecoterror, estimates of the damage to property range from \$50 million to \$200 million over the last 20 years.

One of the largest groups in the United States that has been associated with acts of ecoterrorism is the Earth Liberation Front (ELF). The organization is largely composed of autonomous individuals and smaller groups operating independently, united mainly by shared goals and methods. ELF is also active in Canada, the United Kingdom, and Greece. Individuals linked with ELF have stated

Fire set by arsonists engulfs the Two Elk Lodge in Vail, Colorado, on October 19, 1998. The Earth Liberation Front claimed responsibility for the fire, which they said was a protest against the ski resort's expansion into the habitat of the endangered Canadian lynx. (AP/Wide World Photos)

that their goal is to eliminate profits from businesses that they believe are exploiting or destroying natural resources by taking direct action against these companies, usually through vandalism or arson. ELF has been linked with more than 1,000 acts of vandalism and arson and tens of millions of dollars worth of damage. Prior to the September 11 attacks, the Federal Bureau of Investigation (FBI) ranked ELF as the number one domestic terrorism threat to the United States. Members and sympathizers of ELF object to being labeled terrorists since there have not been any deaths yet associated with their activities. The FBI arrested 18 activists, some of whom are affiliated with ELF, on ecoterrorism-related charges in 2005 and 2006.

The activities of ELF and other ecoterrorist groups are often collectively referred to as monkeywrenching. This is a euphemism for arson, vandalism, and sabotage against construction sites, logging company operations, genetic engineering laboratories, car dealerships, energy companies, and the like. Ecoterrorists also frequently engage in tree spiking, a form of sabotage that involves hammering a metal spike into a tree so that it damages a saw blade attempting to cut the tree down. Saw blades destroyed by tree spikes have been known to cause injuries to loggers; as a result, tree spiking was declared a federal felony in 1988. Some tree spikers mark trees that have been spiked or otherwise notify logging companies of the action as a deterrent to logging operations.

—Andrew Byers

bomb attacks from the 1970s to the 1990s, and various abortion-related violent incidents are representative of the many terrorist attacks that have occurred within the United States in more recent decades.

The Oklahoma City bombing of the Alfred P. Murrah Federal Building occurred on April 19, 1995. In the attack, 168 people died and more than 850 were injured. Until the September 11, 2001, attacks, the Oklahoma City bombing was the deadliest in U.S. history. The two men later convicted of the bombing, Timothy McVeigh and Terry Nichols, were members of the strongly

antigovernment militia movement. They claimed that the attack was in retaliation for heavy-handed and violent government actions in the Waco siege of the Branch Davidian compound in 1993 and the Ruby Ridge standoff in 1992. Both McVeigh and Nichols were arrested and convicted of multiple federal offenses; McVeigh was ultimately executed as a result of his role in the bombing, and Nichols is serving a life sentence. The Murrah Building was destroyed with 5,000 pounds of ammonium nitrate (a fertilizer) hidden in the back of a rented truck. In addition to the numerous deaths and injuries, which included

children at a daycare center in the building, the blast damaged more than 300 nearby buildings. More than 12,000 rescue workers and volunteers were involved in the rescue, recovery, and cleanup operations.

Theodore John “Ted” Kaczynski, who became known as the Unabomber, is an American antitechnology anarchist known for his campaign of mail bombings from the late 1970s through the early 1990s. Kaczynski sent bombs to a number of university employees and airlines officials; his 16 mail bombs killed 3 people and wounded another 23.

In 1995 Kaczynski sent letters to some of his previous victims, demanding that his paper *Industrial Society and Its Future* (commonly called the Unabomber Manifesto), describing the perceived dangers of modern technology and industrialization for modern society, be printed in a major newspaper, and stating that he would then end his bombing campaign. The manifesto was subsequently published in the *New York Times* and the *Washington Post*. Kaczynski’s brother recognized the writing style and notified authorities, who arrested Kaczynski soon thereafter outside his remote Montana cabin. Kaczynski has since been convicted of numerous federal offenses and is serving a life sentence in prison.

Incidents of abortion-related violence have frequently occurred in the United States since the 1970s when antiabortion groups began their protests of abortion policies. These violent incidents have included property crimes such as vandalism, arson, and bombings as well as attacks against abortion providers, including kidnappings, assaults, and murders or attempted murders. Most of these acts have been committed by antiabortion activists against abortion facilities or providers. Those supporting or engaging in such activities commonly explain their actions as justifiable defense in the interest of protecting the life of the fetus.

Violence directed toward abortion providers has killed at least seven people, including doctors, clinic employees, and a security guard. Several of the victims were shot, either at their place of work or at home, and a security guard was killed when his workplace was bombed. Some of these victims were targeted on Web sites prior to the assaults or murders. There have

been dozens of additional attempted murders, kidnappings, and incidents of assault or battery. Death threats are also extremely common. Property crimes are even more common; there have been several hundred bombings and arsons of abortion clinics as well as many lesser cases of vandalism. The most infamous antiabortion bombings were carried out by Eric Rudolph, who committed a series of bombings across the United States, including one at the 1996 Summer Olympics in Atlanta. Rudolph spent years on the Federal Bureau of Investigation’s (FBI) list of most-wanted criminal fugitives but was eventually caught and sentenced to multiple consecutive life sentences.

Basque Terrorists

The Basques, a distinct ethnic group with a distinct language and culture, are the majority population of several provinces in the Pyrenees region of northern Spain and southern France. The Basque insurgency against Spanish rule began in the late 1950s in response to the intensified efforts of the Francisco Franco regime to suppress the use of the Basque language and the practice of Basque customs. The moderate groups that had been advocating Basque autonomy, in particular the Partido Nacionalista Vasco (Basque Nationalist Party, PNV), seemed ineffectual in the face of this escalated oppression, and the Euskadi Ta Askatasuna (Basque Fatherland and Freedom, ETA) movement was formed to present a more radical response.

A further split within the ETA itself occurred in the late 1960s, with the ETA-M (ETA Military Front) separating from the ETA-PM (ETA Political and Military Front). Whereas the ETA-PM sought to combine political activism with selectively targeted violent actions, the ETA-M insisted that

the only effective means for achieving an independent Basque state was terrorism.

The ETA-M has been responsible for most of the subsequent violence in Spain. In 1973 the ETA-M came to international attention with the assassination of the Spanish prime minister, Admiral Luis Carrero Blanco. Over the next 25 years, the ETA-M killed more than 700 people in Spain. More than 60 percent of those killed were members of the Civil Guard, the national police force, but the dead also included assassinated political and military leaders as well as civilians who had been killed randomly in terror bombings.

In 1977 Spain adopted a parliamentary system of government, and in 1980 the federal government allowed direct Basque representation in the federal parliament as well as the formation of a regional Basque parliament. Of the three Basque political parties that have subsequently emerged, the party most closely aligned with ETA-M, Herri Batasuna (Popular Unity, HB), has typically received only 15–20 percent of the Basque votes cast in both regional and federal elections. Clearly, the radical program espoused by ETA-M and its commitment to terrorism have not appealed to more than a minority of the Basques themselves.

In 1987 a combined operation of Spanish and French police eliminated a significant percentage of the ETA-M leadership and seized a sizable cache of weapons and other resources. And yet the core membership of ETA-M has demonstrated a continuing intense commitment to its cause that seems to depend as little on the presence of particular leaders as on widespread popular support. Although the ETA-M's acts of terrorism became more intermittent in the 1990s and diminished dramatically after the September 11, 2001, terrorist attacks against the United States, they have occurred with enough regularity to convince investigators that the group has maintained its operational capabilities and still poses a considerable threat.

➤ BASQUE TERRORISTS AND MARCH 11, 2004

In the initial response to the March 11, 2004, Madrid train bombings (also known as 3/11), the Spanish government under the center-rightist Popular Party (PP) initially blamed the Basque Euskadi Ta Askatasuna (ETA). Almost immediately after the bombings occurred, the Spanish government claimed that evidence pointed at ETA involvement in the terrorist attack that had resulted in the deaths of 191 people and the wounding of another 1,755. Later investigations showed that it was not the ETA but rather Islamic terrorists with alleged links to al-Qaeda composed of Moroccans, Syrians, and Algerians allegedly angered at Spain's involvement in the Iraq War. The PP lost its majority in the elections later that month to the center-leftist Partido Socialista Obrero Español or Spanish Socialist Workers' Party (PSOE), as many in the Spanish public felt that the bombings were a result of Spanish involvement in the unpopular war. Nevertheless, this episode shows how many in Spanish society were ready to cast blame on the ETA as they were the group typically associated with terrorism in Spanish society.

European Terrorists—Red Brigades, Red Army Faction, and the Irish Republican Army

European terrorism emerged from the tumult of the late 1960s when various ideologically driven organizations of armed militants set about to destroy their respective states, either to provoke a fascist response or to secede from colonial hegemony. The Red Brigades in Italy and the Red Army Faction (RAF) in West Germany, both formed by former student radicals fueled

➤ MUNICH: SEPTEMBER 5, 1972

During the 1972 Munich Olympic Games in West Germany, 8 Palestinian terrorists were responsible for the murder of 11 members of the Israeli Olympic team taken as hostages. In total, all 9 athletes, 2 coaches, 5 terrorists, and 1 police officer were dead after the disaster ended. The games were meant to reconcile the Germans and the Israelis, this after several decades had passed since the end of World War II and the Holocaust. The Palestinian terrorists, affiliated with the Black September organization, had ties with the leftist German terror group the Red Army Faction (RAF), having trained together in Middle East camps along with Basques, Italian Red Brigades, and the Irish Republican Army. This event illustrated the transnational ties that existed between European and Middle Eastern terrorist organizations.

—*Abraham O. Mendoza*

by Marxist or nationalist discourses, believed that if pushed hard enough, their respective democratic regimes would impose repressive measures and show their true fascist structures. The nationalist Irish Republican Army (IRA) in Northern Ireland, much like the Basque secessionists in Spain, believed that through acts of terrorism on British military, civil, and civilians they would better persuade the British government to cede Northern Ireland to Greater Ireland, liberating Ireland completely from the British yoke.

The Red Brigade (Brigate Rosse) was a fringe left-wing terrorist organization in Italy during the 1970s, emerging from the historically radical leftist city of Milan. The Red Brigade committed repeated acts of terrorism in order to ignite Marxist revolution and thus bring about a socialist transformation of Italian society. From 1972 to 1983 the Red Brigade was responsible for terrorist attacks against Italian politicians and businessmen, American military installations, and the police. In addition to bombings perpetrated by right-wing groups, the Red Brigade's activities made the 1970s known in Italy as the years of bullets (*anni di piombo*). In 1976 the Red Brigade murdered 8 and seriously wounded 16. The

following year the organization was responsible for the murders of 7 people and the wounding of 40. In 1978 the Red Brigade was responsible for the kidnapping and murder of former prime minister Aldo Moro, its most infamous action. Rather than instigating a revolution, the Red Brigade's actions provoked severe government repression and created popular suspicion of leftist student and labor organizations.

Similar to the Red Brigade, the RAF was a German terrorist group with Marxist-Leninist leanings founded in 1968 by Andreas Baader, Ulrike Meinhof, Gudrun Ensslin, and Horst Mahler out of the more radical wing of the German Socialist Student Alliance (SDS), heavily composed of anarchist students of middle-class background. Subsequently, the RAF began a terrorist campaign characterized first by bank robberies and ransom kidnappings, eventually escalating to attacks on West German, North Atlantic Treaty Organization (NATO), and U.S. targets through bombings, assassinations, kidnappings, and acts of sabotage. In 1977 the RAF kidnapped and murdered West German industrialist Hanns-Martin Schleyer, its most infamous action. However, the RAF's hijacking of a German airliner in 1977 resulted in repressive government legislation in the form of antiterrorism laws and more intense policing measures. Since then, most RAF leaders have been captured or have committed suicide.

Through much of the early twentieth century, the IRA sought to dislodge Catholic Northern Ireland from Protestant Great Britain through political and armed action after having successfully ensured the independence of the Irish Free State in 1921 (Republic of Ireland, 1948). In 1969, violence erupted in Northern Ireland, resulting in the split between the political and the militarist factions of the IRA. The militarists formed into the Provisional IRA, while the political faction became known as the Officials, which suspended the use of violence in 1972. The Provisional IRA sustained an active campaign of violence for decades, with its objective being to make the province of Ulster (Northern Ireland) ungovernable and force British troops to withdraw their support of the Protestant majority. Between 1973 and 1993 the IRA carried out 487 bombings and 28 shootings in Britain in an attempt to weaken

British resolve. Armed clashes also continued in Northern Ireland with an average death toll of 100 a year. Conciliatory actions between the IRA and the British government in the 1980s came to nothing, and violence continued. However, in the Good Friday Agreement (April 1998), the IRA agreed to participate in a decommissioning process and on July 28, 2005, agreed to pursue only political means to ensuring Northern Ireland's independence. Growing international involvement

and domestic discontent with violence contributed to the wane in militancy.

■ Introduction: Militarization and Peace Movements

Many would argue that well-funded militaries offer stability to nations in a world of dangerous adversaries that include terrorists and rogue states armed with the means of gaining access to nuclear or biological weapons. Others would argue that military spending and the militarized mind-set only encourage the rise of dangerous adversaries and a self-perpetuating march toward violence. One of the most remarkable historical shifts of the modern period is the growth of the U.S. military and military expenditures since 1941. World War II and the Cold War that followed transformed the United States from a minor military power to one with at least seven times the annual budget of any rival military in the world, creating, in effect, a permanent wartime economy in the United States. Dwight Eisenhower, the supreme commander of Allied Expeditionary Forces in Europe during World War II and a Cold War-era president (1953–1961), left office warning of the dangers of the military-industrial complex. This speech made him an unlikely critic of the myriad connections between the U.S. military and its universities and corporations. Following the collapse of the Soviet Union, there was general discussion of a peace dividend in the United States, but military spending instead remained high. The terrorist attacks of 2001 in the United States, the 2004 bombings in Madrid, and the 2005 bombings in London encouraged this militarized mind-set in the United States and Britain. As of 2008, according to the Stockholm

International Peace Research Institute, the \$607 billion in military spending by the United States encompassed 41 percent of the world's total; China, with \$84.9 billion in military spending, was a distant second, with 5.8 percent of the world's total. Since 2001, major sporting events in the United States tend to feature flyovers of fighter jets and other patriotic nods to the military. Discussions of the appropriate use of torture, common in the past decade, would be unheard of decades ago.

Peace movements have been many, including the (failed) international scientists' movement to ban nuclear weapons, other antinuclear coalitions such as the National Committee for a Sane Nuclear Policy (SANE), the international Nuclear Freeze movement, and various groups that have protested wars ranging from the U.S. war in Vietnam to the Persian Gulf wars of more recent decades. Peace Studies is now a fledgling academic discipline, underpinned by such notions as those expressed by Herbert Marcuse in *One Dimensional Man* (1967) that modern society is encoded with a rationality gone berserk; that is, research and the rational systems of technology are premised on irrational ends (leveling cities with nuclear weapons or designing weapons that will kill people but not destroy property, as two examples). The apparatus of national security states forged following World War II neatly dovetailed military concerns with civilian control. This merge has become only more apparent following the September 11, 2001, terrorist

attacks as governments extend their intelligence gathering of citizens' communication in the name of public safety and national security, as police and intelligence agencies share information, as cyberspace become militarized, as modern police forces borrow military hardware and procedures, and as public space is placed under surveillance.

—*Fred Nadis*

Military-Industrial Complex

Before World War II, the United States mobilized only after its wars began. During the Cold War, however, the United States and the Soviet Union shifted to a constant state of military preparedness, maintaining large combat-ready military forces and nuclear arsenals. The sum total of the academic, industrial, and government institutions that evolved to meet the requirements of Cold War deterrence and defense has been called the military-industrial complex (MIC). President Dwight D. Eisenhower first used the term in his 1961 farewell speech when he warned against excessive military and defense industry influence on the scientific world, academia, and democratic processes. Some observers describe the MIC as an iron triangle of beneficial relationships among the Defense Department, legislators with jurisdiction over defense programs and budgets, and defense contractors.

Creating and improving superior military forces during the long Cold War competition with the Soviets required relentless scientific, technological, and engineering innovation. To promote this innovation, the Defense Department sponsored basic and applied research, development, testing, evaluation, and experimentation in academic and industrial laboratories. Government funding of U.S. research and development (R&D) exceeded private industry funding until the early 1980s, and defense generally dominated federal R&D funding after 1945, especially from 1945 until 1963. Defense research declined as a proportion of federal R&D after the Vietnam conflict but jumped again (from 49 percent to 70 percent) between 1980 and 1987 largely because of research on the Strategic Defense Initiative (SDI), which proposed to create space-based defenses against intercontinental ballistic missile

attack. Universities performed most of the basic defense research, and private industry conducted most of the applied research for SDI. Defense-related industries consistently received about 80 percent of all federal funding for manufacturing R&D from 1945 to 2002, with most of the funds concentrated among the largest contractors.

During the Cold War, the U.S. government cooperated closely with defense industries, funding plant construction, providing guaranteed markets, protecting weak firms, and promoting exports. The government cultivated an oligopolistic defense industry in which relatively few aerospace, electronics, and communications firms provided small numbers of highly specialized products to a single customer that cared more about quality than cost. Defense projects represented about 6–10 percent of the private-sector workforce but employed more than half of the nation's aerospace engineers and one-quarter of all electrical engineers and physicists. Defense work also employed large numbers of highly skilled blue-collar workers, particularly aircraft and electronics assemblers, machinists, metalworkers, shipfitters, and aircraft mechanics.

Defense corporations usually hired retired military officers, who had excellent institutional knowledge and personal contacts inside the military, to market to the Pentagon. Defense corporations subsidized lobbying groups and contributed heavily to selected political campaigns. In the 1990s, defense lobbyists urged Congress to provide tax exemptions for arms exporters, issue government-backed loans to countries importing American weapons, and lift bans on arms sales to repressive regimes. Defense corporations often organized grassroots lobbying efforts for particular weapons systems that were in danger of cancellation.

The MIC conferred mixed benefits on the U.S. economy and society. It created a military that deterred Soviet aggression and prevented nuclear war, and it ensured U.S. leadership in aerospace, computer, communications, and electronics technologies. Commercial products or ventures that emerged from the MIC included jet engines as well as the widespread civil aviation after the invention of radar, lasers, microchips, computers, satellites, robotics, and the Internet. However, the MIC imposed enormous financial, political, and

➤ EXCERPT FROM DWIGHT D. EISENHOWER'S FAREWELL ADDRESS, JANUARY 17, 1961

"Until the latest of our world conflicts, the United States had no armaments industry. American makers of plowshares could, with time and as required, make swords as well. But now we can no longer risk emergency improvisation of national defense; we have been compelled to create a permanent armaments industry of vast proportions. Added to this, three and a half million men and women are directly engaged in the defense establishment. We annually spend on military security more than the net income of all United States corporations.

This conjunction of an immense military establishment and a large arms industry is new in the American experience. The total influence—economic, political, even spiritual—is felt in every city, every Statehouse, every office of the Federal government. We recognize the imperative need for this development. Yet we must not fail to comprehend its grave implications. Our toil, resources, and livelihood are all involved; so is the very structure of our society.

In the councils of government, we must guard against the acquisition of unwarranted influence, whether sought or unsought, by the military-industrial complex. The potential for the disastrous rise of misplaced power exists and will persist.

We must never let the weight of this combination endanger our liberties or democratic processes. We should take nothing for granted. Only an alert and knowledgeable citizenry can compel the proper meshing of the huge industrial and military machinery of defense with our peaceful methods and goals, so that security and liberty may prosper together."

The Globalization of the Defense Industry

Defense industries were, by necessity, internationalized before World War I. At that time only Britain, France, and Germany possessed full industrial capacity to produce modern weapons, and even other Great Powers (Austro-Hungary,

Italy, Japan, the Russian Empire, and the United States) were dependent on imports for a significant part of their armaments and materiel. Moreover, given the competition between the major powers, weapons were frequently imported from opposing alliances. Japan relied on British yards for its navy and on German factories for its artillery; Russia ordered cruisers in England and Germany and armed home-built vessels with French light guns.

The rupture associated with World War I—Germany's defeat, the collapse of world trade, local nationalism, the rise of the United States and of the Soviet Union with its autarchic economy—fragmented the world arms market. Internationalist inclinations of the elites on the eve of World War I were replaced by nationalist hysteria and a cult of military secrecy. By the beginning of World War II, major combatants possessed predominantly domestic weapons. Even armaments, transferred to the Soviet Union and Great Britain by the United States through Lend-Lease or given by the Germans to Romania, Hungary, or Finland, were rarely state-of-the-art equipment.

➤ NUCLEAR PROLIFERATION

“I am haunted by feeling that by 1970, there will be 10 nuclear powers instead of 4, and by 1975, 15–20.” John Kennedy, 1963.

Alongside the legal transfer and acquisition of weapons and military technology, there exists its illegal companion, called proliferation. The conventional view that the policy of nonproliferation of nuclear weapons has been an expensive failure ignores the evidence. As of 2007, only eight states (the United States, Russia, the United Kingdom, France, China, Israel, India, and Pakistan) credibly possess nuclear weapons, while a similar number of states terminated their nuclear-weapons programs either unilaterally or under pressure from the world community. In the 1990s three Soviet-successor states—Belarus, Kazakhstan, and Ukraine—returned ex-Soviet nuclear weapons to Russia, while South Africa destroyed already-produced nuclear devices. All four acceded to the Non-Proliferation Treaty (NPT) as nonnuclear states.

—Peter Lerner

The onset of the Cold War and the withdrawal of France and Britain from global competition in 1954–1956 in the aftermath of the Indochina and Suez crises created the conditions for the formation of an essentially duopolistic system. The two superpowers supplied major weapons and technologies to their allies and client states, frequently on a noncommercial basis. Since the 1970s the North Atlantic Treaty Organization (NATO) had conducted extensive standardization of its arsenals, thought by many as an attempt to impose American technologies and priorities on its European allies. Yet this multibillion-dollar process was probably highly beneficial for both the United States and the European members of NATO. By the end of the Cold War, the United States and the Soviet Union controlled approximately 70 percent of the trade in conventional weapons (\$119 billion out of \$173 billion during 1985–1989).

By the 1970s, intensifying competition led to export offerings of systems that were as advanced as (or more advanced than) those being supplied to the national armed forces (e.g., Ira-

nian orders of US F-14s, Kidd destroyers, and British Chieftain tanks). The Soviet-Chinese split created an independent market in the copycat designs of lower-tech weapons. Another end of the Cold War phenomenon was offsets: investments, transfers of technology, and production capacity were provided as enticements to potential customers (e.g., the F-16 was coproduced in five countries, including Turkey and the Netherlands).

Globalization of defense production was closely related to the consolidation of domestic U.S. and European Union (EU) industries: the world market became too small for the Cold War establishments. As a result of the mergers and acquisitions activity in the 1990s (\$21.5 billion in 1995), the bulk of defense production in the United States was concentrated in four conglomerates: Boeing, Lockheed Martin, Northrop Grumman, and Raytheon. By 2000, consolidation of the prime contractors in the United States was almost complete. For example, while 13 separate contractors were involved in tactical missile construction in the United States in 1990, in 2000 there were only three.

The collapse of the Soviet Union brought the previously smaller-size European and Israeli companies to the forefront of the new global defense industry. The EU also tried to force consolidation of its defense industry. In particular the Airbus, Eurocopter, and Eurofighter programs were united in the holding the European Aeronautic Defense and Space Company (EADS) (majority owned in 2006 by Daimler Chrysler, Spanish SEPI, French Group Lagardère, and the French government; concluded a transatlantic alliance with Northrop). The tactical missile program of EADS was managed by MBDA, created by the merger of French Matra, UK BAE, and Italian Alenia. In 2000, European defense contractors owned approximately 200 subsidiaries in the United States. Foreign ownership of defense companies became accepted in previously nationalistic South Korea, South Africa, and Brazil.

The consolidation of defense industries has gone hand in hand with internationalization of production. While the United States and the EU still procure main weapons platforms from domestic manufacturers, contracts for subsystems, components, and spare parts are more globally

dispersed. This process will only accelerate in the future with the further growth of software and computer-aided design (CAD) in proportion to total cost. For example, with some reluctance, the U.S. Air Force noted that the software development for its newest fighter, the Raptor, had been partially outsourced to India. However, the defense industry is unlikely to become completely transnational. Even among allies there are obstacles: state regulations, the desire to maintain domestic manufacturing base, and the vagaries of a national budgeting process. Yet globalization is likely to continue, transcending the borders of the military and commercial blocs. A consortium of Russian banks acquired a minority stake in EADS in 2006. The Ukrainian Space Agency, Norwegian Aker, and Russian NPO Energy formed a Sea Launch JV with Boeing. In 2004 China offered to Pakistan a reconnaissance system based on a Russian-built plane and Israeli radar.

While the globalization of design and production of weapons and space systems has no parallels in history, the political landscape has become strangely reminiscent of pre-World War I times. Weapons production has become concentrated in a few giant conglomerates, while the national and political affiliation of weapons supplier once again has lessened in importance.

—Peter Lerner

The National Security State

The national security state emerged in the years immediately following the end of World War II as parties on both sides of the Iron Curtain prepared for possible military conflict. The national security states likewise developed as Cold War

participants prepared for possible subversion stemming from without by foreign agents and from within by saboteurs and traitors. Both superpowers, the United States and the Soviet Union, through their domestic and foreign intelligence offices and those of their allies and satellites (such as the notorious STASI in East Germany), created intricate surveillance infrastructures and procedures to prevent foreign and domestic infiltration and espionage. The tense climate of the Cold War legitimized the expansion of the police powers of the state and the normalization of questionable practices violating civil and political rights. The arms buildup in the form of increasing government expenditures on new systems of nuclear weapons and massive conventional stockpiles of modern war materiel were also a fundamental characteristic of the emerging national security state.

Under the Harry S. Truman administration, the importance of national security in the United States was highlighted with the passing of the National Security Act in 1947, which created two new institutions—the Central Intelligence Agency (CIA) and the National Security Council (NSC)—while also dramatically expanding the Federal Bureau of Investigation (FBI). By 1950, the U.S. NSC presented the Truman administration with NSC-68, titled *U.S. Objectives and Programs for National Security*, presenting the case for prioritizing the Cold War as the primary foreign policy objective. The document urged more rigorous domestic and foreign surveillance by intelligence services and urged political, economic, military, and diplomatic engagement globally to counter and contain the Soviet threat.

At the same time, the House of Un-American Activities Committee (HUAC), established in 1938 to investigate New Deal programs and their implementation, began to focus in 1947 on investigating communist activity in the United States. FBI director J. Edgar Hoover gave the committee new life when he testified that there was a new Red Menace in the United States. In an ensuing high-profile investigation, HUAC scrutinized the U.S. entertainment industry, which resulted in the blacklisting of many writers, directors, and actors with alleged communist sympathies. HUAC's actions revived various federal and state governmental loyalty committees. Amid this

► MILITARIZATION OF SPACE

One of the main impetuses for forging the space programs in both the United States and the Soviet Union was the desire to develop weapon delivery systems for nuclear warheads and improve surveillance in the context of the Cold War. The launch of Sputnik in 1957 by the Soviets triggered the space race between the superpowers. In response, the National Aeronautics and Space Administration (NASA) was established in the United States by the 1958 National Aeronautics and Space Act. Advances made by both sides, in terms of satellite technology involving communications, reconnaissance, and surveillance capabilities, led to the potentiality of the militarization of space as the technology advanced to the point when it was possible to launch missiles from satellites.

In addition to prompting successful orbits around the earth, landing men on the moon, and scientific research, the space race also contributed to advances in weapons systems, such as the Intercontinental Ballistic Missiles (ICBM) and Anti-Satellite Weapons (ASATs) in the decades following the launch of Sputnik. To better cover large distances, ICBMs are launched into sub-orbital spaceflight. However, the ability to use these weapons from space or in space caused severe concerns among an already tense public during the Cold War. This led to the Outer Space Treaty of 1967, which prohibited the stationing of nuclear weapons in space but did not ban ground or air attacks on satellites.

In 1983, U.S. president Ronald Reagan proposed the Strategic Defense Initiative (SDI), nicknamed “Star Wars” after the popular series of films by George Lucas. Edward Teller, who oversaw the development of the hydrogen bomb in the United States, conceived SDI as a defense system that would rely on ground-based and space-based systems (using lasers) to protect the United States from attack by Soviet ICBMs. Despite domestic and international criticism, SDI-related research received enormous government funding. At the end of the Cold War, defense spending was reduced, and space research emphasized a scientific, not a military, agenda. In 2002, however, U.S. president George W. Bush signed the National Security Presidential Directive that rejected U.S. participation in the 1972 ABM Treaty with the USSR and promoted efforts to deploy operational ballistic missile defense systems by 2004, utilizing extensive satellite technology for global positioning weapons capabilities and nuclear weapon detection. Other countries, such as Russia, China, and India, continue to launch and conduct research on spy satellites. In January 2007, China successfully shot down one of its aged weather satellites in a clear announcement that China was no longer a bystander in the militarization of outer space and had the means to shoot down surveillance satellites.

—*Abraham O. Mendoza*

atmosphere of paranoia, schoolteachers, university professors, and other state employees were scrutinized for loyalty, while federal employees were subjected to FBI background checks, with many homosexuals, for example, being forced to resign from federal positions as security risks.

Control of possible subversives in the Soviet Union relied on starker methods. From the late 1940s to the mid-1950s, the Soviet Union began to exile and incarcerate many of its returning soldiers from Europe, sending many of them to the Gulag camps in Siberia as political criminals infected with Western ideas. Many top Soviet officials were labeled as American spies and Zionists and, in an atmosphere of heightened suspicion, were purged from the party either

by exile or murder. The myriad responsibilities of the *Komitet Gosudarstvennoy Bezopasnosti* (KGB), Committee of State Security (previously known as the NKVD), included foreign and domestic espionage, intelligence, counterintelligence, maintaining networks of informers and police authority over the domestic population, protection of the nation’s borders, and covert activities and disinformation within and outside the Soviet Union. The KGB maintained constant surveillance over the Soviet population from 1954 to 1991. The KGB also worked with foreign intelligence services in the Eastern Bloc countries.

In the United States, the newly founded CIA, taking over from the disbanded Office of Strategic Services (OSS), became responsible for

gathering foreign intelligence and compiling strategic reports for the federal government. The CIA influenced foreign policy decisions and conducted covert operations (ops) abroad. One example of such covert ops, which flourished during the Dwight D. Eisenhower administration, was Operation Ajax in which the CIA staged a 1953 coup against Iranian leader Mohammad Mosaddeq, suspected of Soviet sympathies, and restored the pro-American authoritarian shah. At the same time, the FBI, under the authority of J. Edgar Hoover for nearly four decades, was responsible for domestic intelligence. Overstepping its mandate, the FBI's Counterintelligence Program (COINTELPRO), begun in the mid-1950s, ensured the surveillance of not only underground subversive groups but also oppositional and activist organizations such as those advocating civil rights for black Americans.

Both Cold War opponents also invested massive amounts of their national wealth on developing weapons systems, particularly in the form of nuclear weapons, and their respective armed forces and those of their allies. In the four decades following World War II, both superpowers developed atomic and hydrogen weapons as well as delivery systems such as Intercontinental Ballistic Missiles (ICBMs), Multiple Re-entry Vehicles (MRVs), and suitcase bombs. They also forged alliance systems—the North Atlantic Treaty Organization (NATO) and the Warsaw Pact—to counter each other's advances.

Even after the fall of the Soviet Union and much of the socialist Eastern Bloc from 1989 to 1991, which spelled the end of the communist threat, the powers secured by the national security state have continued unabated, particularly as seen in the United States and in Russia, again, under the authoritarian President Vladimir Putin. Many other governments across the world continue to use national emergencies as a pretext to circumscribe civil rights and to augment national police powers against external (i.e., global terror networks such as al-Qaeda) and internal enemies (i.e., Islamic fundamentalists, separatists). Most recently, the September 11, 2001, attacks on the United States resulted in the creation of the Department of Homeland Security and the establishment of the USA PATRIOT Act (Uniting and Strengthening America by Providing Appro-

priate Tools Required to Intercept and Obstruct Terrorism Act of 2001), which some critics allege provides tools to constrict U.S. civil liberties and therefore create dangerous precedents. In the revived atmosphere of heightened security, there also has been controversy over U.S. military authorities alleged human rights abuses against suspected armed combatants at Abu Ghraib prison in Baghdad and in Guantanamo Bay in Cuba.

At the same time, countries such as Russia, Venezuela, and China have increased the power of their state police forces in response to internal developments and perceived foreign subversion in a post-Gulf War and post-9/11 world of heightened vulnerability and suspicion. However, strong police state internal surveillance does not constitute the only element in the existing definition of the national security state. Experts would also insist that a security state include increased spending on arms and weapons systems—the case in Iran—but not, for example, in the police state of Argentina in the 1980s during its so-called dirty war.

Military and Corporate Patronage at Universities

During the second half of the twentieth century, higher education in the United States and elsewhere underwent a radical transformation. Enrollments skyrocketed, and student populations became more diverse ethnically and racially. Faculty research became enmeshed in larger, more collaborative projects. Curricula expanded as interdisciplinary approaches to knowledge gave rise to area studies and special interest topics. Campuses themselves began to take on a new look, with architectural innovations making their

way into dorm life and classroom design. Universities of the first half of the century shared little in common with those of the second half. One of the leading factors that contributed to this transformation had to do with a change in how these institutions were funded, particularly from such sources as the military and the private sector.

Military patronage affected change in higher education largely through significant increases in funding for faculty research. Research ties among academic scientists, universities, the military-industrial complex, and government agencies forged during World War II continued during the Cold War, particularly in America and the Soviet Union, where national defense fueled increasingly larger scientific projects. After the Manhattan Project (the project to develop the first nuclear weapon) came the research, design, and development of other weapons of mass destruction, such as the hydrogen bomb and the neutron bomb. These and similar projects, as developed by at least the Cold War superpowers, required high levels of organization, military funding, and, in many cases, secrecy. Certain institutions, such as Stanford and the Massachusetts Institute of Technology (MIT), developed better relations with the U.S. Department of Defense than others, depending on the university's culture and leadership. Harvard's president, James Conant, for example, was less comfortable with the idea of applied classified research than was MIT's Karl Compton. By 1960, U.S. agencies funded research at a price tag of more than \$5 billion a year.

Many other nations developed strong relations between the military and universities. Australia increased defense-related research on its campuses in the decades following World War II. The Manhattan Project served as an important model for coordinating Australian university and military resources. University scientists in Brazil received a significant boost from the country's military and political leadership with the founding of the Synchrotron Light National Laboratory in the 1980s. In other countries, military patronage or influence redirected resources for specific purposes. Italian science became predominately focused on physics (as opposed to other physical, biological, and social sciences) as a result of

Department of Defense Funding of University Research Science and Engineering

During the early period of the Cold War, the U.S. Department of Defense provided steady funding for university-based scientific and engineering research projects. Beginning in the late 1970s, this funding dramatically increased and continued to increase after the so-called end of the Cold War in 1989.

—A.J. Angulo

military and governmental funding. Turkish space science since the 1970s has been supported by a web of military and private sources. Due to the influence of the military in shaping policy, however, the establishment of a Turkish space agency was thwarted throughout the end of the twentieth and early twenty-first centuries.

As with military-university relations, funding from the private sector also influenced changes in post-World War II faculty research. The United States and Japan followed two different models of corporate-university relations that other nations adopted. In the United States, universities conducted both basic and applied research. Whatever the source of funding, the two could be found on most campuses. The locus of Japanese scientific research, however, has centered in the private industrial laboratories. In India and China, concerted efforts to unite industry and universities in research resulted in specific developments such as the creation of technology research parks, the standardization of contracted research, and increases in government investment for collaboration. A turning point for American university-industry relations came with the passage of the Bayh-Dole Act of 1982, otherwise known as the Patent and Trademark Amendments Act. The passage of this bill allowed universities that conducted federally funded research to claim patent

rights and licenses. With these rights and licenses came a sharp increase in interest from both universities and industry to commercialize products resulting from government-funded research.

Pacifist Movements— Japan and Costa Rica

Following World War II, the governments of Costa Rica and Japan both created pacifist constitutions in an undemocratic manner; nonetheless, these constitutions have aided the stability of their democracies and greatly enhanced both nations' economic development.

Costa Rica's national policy of pacifism began after the brief Costa Rican Civil War (March 11–April 24, 1948), which brought victory for coffee businessman-farmer José Figueres Ferrer (1906–1990) and the Partido Union Nacional and exile for most of the Calderon-Picada government. As the military dictator of Costa Rica (April 1948–November 1949), Figueres drafted a new constitution that abolished the army, established a public police force, and subordinated all police power to civilian authority in its Article 12. President Otilio Blanco Ulate (1871–1973) finished the abolition of Costa Rica's national military in 1950, completing that country's transition to pacifism.

Costa Ricans' commitment to pacifism and the absence of a military have contributed to a political stability and economic prosperity unmatched in Central America. When rebel forces led by exiled Rafael Calderon Guardia (1900–1970) invaded Costa Rica from Nicaragua in January 1955, President Figueres turned to other American nations for aid. In negotiations with the Organization of American States (OAS) and U.S. politicians, Figueres invoked Article 2 of the nonaggression pact of the 1947 Rio Treaty committing signatory nations to peaceful settlements and subordination to the Inter-American System. Convinced by Figueres's argument, the OAS requested that the United States send fighter planes to Costa Rica, a move that marked the end of the Calderon junta.

Costa Rica continues today to rely on pacifism for its national security. U.S. president Ronald Reagan encouraged the fortification of the Costa Rican national police to counter the Nicaraguan Sandinistas' threat in the early 1980s. The end of the Contra War in Nicaragua, El Salvador, and Guatemala, however, came through the 1987 Peace Plan of Costa Rican president Oscar Arias Sanchez, who won the Nobel Peace Prize (1987). Costa Rica initially supported the forceful overthrow of Iraqi dictator Saddam Hussein in 2003. However, the Costa Rican Supreme Court ruled that this support was an unconstitutional act that also violated international law, and Costa Rica then withdrew its moral support for the invasion of Iraq.

Costa Rica's reputation for pacifism attracted Jewish refugees from the Third Reich during and after World War II and Quaker conscientious objectors from the United States during the Vietnam War. The Quakers have established a community at Monteverde, still known today for its pacifism, where they have been joined by Mennonites, Beech Amish, and other pacifist groups. U.S. and other American tourists have now made Costa Rica a popular destination.

While the pacifist constitution of Japan developed in the aftermath of World War II, the Japanese pacifist movement first began in the late nineteenth century among Japanese Christian and socialist intellectuals who opposed Japanese militarism. Quaker Nitobe Inazō (1862–1933), a student of American Dr. William S. Clark at his

➤ POST-HIROSHIMA JAPANESE PEACE MOVEMENT

Japanese pacifism was reborn in 1945 as an antiwar and antinuclear peace movement from the atomic ashes of Hiroshima and Nagasaki. The Japan Socialist Party (JSP) remains the most vocal proponent of the general disarmament outlined in Article 9 of Japan's postwar constitution and a nuclear weapons ban. JSP chairman Suzuki Mosaburō (1893–1970) and Christian socialist professor Tabata Shinobu (1902–1993) fought to defend Article 9 against pressure on Japan, from both conservative Japanese politicians and the Supreme Command of Allied Powers, to rearm and combat Asian communism. Major protests erupted after the U.S.-Japan Security Treaty (January 19, 1951) stationed U.S. troops throughout Japan. That year 8,000 fishermen also demonstrated against U.S. nuclear testing at Bikini Atoll, galvanizing the housewives and schoolteachers who founded the Japan Council Against Atomic and Hydrogen Bombs (Gensuikyo) in 1955. Students, the JSP, the General Council of Trade Unions (Sohyo), teachers, and housewives surrounded the Diet in objection to the U.S.-Japan Treaty of Mutual Cooperation and Security (Anpo) signed on January 19, 1960. The Anpo protests denounced the nation's remilitarization and both the stationing and extraterritoriality of U.S. soldiers in Japan stipulated in the treaty. Gensuikyo, led by Professor Yasui Kaoru, organized the first annual World Conference Against Atomic and Hydrogen Bombs in Hiroshima (1963) and remains Japan's most prominent antinuclear organization. The year 1963 also marked the beginning of Hiroshima Day (August 6) as a national holiday and of television programs, artwork, and performances depicting wartime tragedies. Under Prime Minister Satō Eisaku (1964–1972), the National Diet signed the Nuclear Non-Proliferation Treaty (1968) and adopted the Three Non-Nuclear Principles against the production, possession, and importation of nuclear weapons (1971). Today Japan maintains its antinuclear position, while the United States, other United Nations members, and conservative Japanese nationalists pressure the nation to play a military role in international disputes appropriate to its economic status.

—Garrett Washington

new Sapporo Agricultural College in the early 1880s, and his American Quaker wife Mary El-kinton (1857–1938) promoted U.S.-Japan relations and international pacifism. Uchimura Kanzō (1861–1930), by far Japan's most well-known Christian pacifist and Nitobe's classmate in Sapporo, became Japan's most vocal critic of the military's expansion in China and Korea through articles in the daily *All Things Morning News* and his own monthly magazine *Studies on War*.

Japanese Christian and socialist professors shaped the pacifism of their students. Before being forced to resign from Tokyo's Number One High School for refusing to show reverence to the ultranationalist 1891 Imperial Rescript on Education, Uchimura led some students, including political scientist Yanaihara Tadao (1893–1961), toward pacifism. Yanaihara echoed Uchimura's prophecy of Japan's devastation by war. Tokyo Senmon Gakkō professor Abe Isoo (1865–1949), often called the father of Japanese socialism, actively opposed militarism in his courses and articles. Abe's students at Tokyo Senmon (now Waseda University), including Saitō Takao (b. 1936), revived the Japan Socialist Party (1945) with Abe as adviser. They strongly opposed Japanese rearmament.

During and after World War II, champions of pacifism became even more outspoken. Christian pacifist Kagawa Toyohiko (1888–1960) aimed to avoid war with the United States through the Christian Peace Mission (1941), founded the International Peace Society (1945), and earned a Nobel Peace Prize nomination in 1955. While the U.S.-dominated Supreme Commander of Allied Forces' Government Section drew up the postwar constitution for Japan, ardently pacifist Japanese prime minister Shidehara Kijūrō (who served during October 1944–May 1946) wrote Article 9, stipulating Japan's disarmament and renunciation of war.

Dōshisha University president and professor of political science Tabata Shinobu (1902–1993), the leading postwar Japanese pacifist scholar, encouraged socialist antirearmament Diet member Doi Takako (b. 1928) and other students to embrace pacifism. Tabata's National League to Defend the Constitution, People's League to Prevent Constitutional Revision, and Institute of the Japanese Constitution at Dōshisha continue with

Doi to uphold Article 9 of the postwar constitution of Japan against Liberal Democratic Party proponents for rearmament. As of the spring of 2007, Japanese politicians revived the debate over revising the pacifist articles in the 1947 constitution.

Pacifism and Anti-Vietnam Protests

The Vietnam War was America's longest-lasting military conflict and remains arguably its most controversial. Protests eventually helped force a reassessment of the U.S. conduct of the war. Activists' reasons for opposing the war ranged from pacifism to political, ethical, and religious objections. Protesters often voiced their opposition through traditional demonstrations such as rallies and parades. The small number of Americans who were more specifically pacifists, and not just against the war in Vietnam, were matched by Buddhists in South Vietnam. Antiwar literature from war opponents ranged from materials supplied by pacifist groups (including Quakers), some communist front organizations, and other groups and individuals who argued that the war

On June 11, 1963, Buddhist monk Thich Quang Duc immolated himself on a busy Saigon street. Malcolm Browne's photograph was taken as Thich Quang Duc burned to death after gasoline was poured on him by two fellow monks. The photo, widely publicized by the American press, brought religious protests against the war to the forefront. (AP Photo/Malcolm Browne)

was unjust. While this was not the first time that the United States saw significant antiwar protest, the protests left a significant legacy. The U.S. military moved away from the draft and became an all-volunteer force, and later U.S. presidents have been more cognizant of public opinion when committing forces abroad.

Early in the conflict, the majority of Americans supported involvement in Vietnam. However, as the casualties increased and the objectives became less clear, Americans began to question their leaders. In early 1966, the antiwar movement grew in force and numbers, and people began to demonstrate more publicly. During this time, picketers were constantly marching in front of the White House chanting rhymes such as "Hey, hey, LBJ, how many kids did you kill today?" Due to their increasing numbers and the liberal climate found on most campuses, college students became one of the most important forces in the movement for peace. Eventually, veterans of the war became another important contingent that effectively argued for the pursuit of peace. One of the most important such organizations was the Vietnam Veterans Against the War (VVAW). Originally, there was tension between veterans and most protest groups, but as the war dragged on many veterans against the war began to earn the respect of other objectors.

Since the draft was in effect during Vietnam, many Americans eligible for military service chose to physically desert by relocating to Canada. Although women were not eligible for the draft, many men who headed north across the border were accompanied by women whose antiwar convictions were equally strong. Others chose to avoid the draft in more traditional ways, such as seeking educational or medical deferments. President Bill Clinton is perhaps the most famous of these draft dodgers and remained outspoken in his opposition to the war.

It must be noted that there is a distinction between those who were established pacifists (people opposed to all wars) and those Americans who were specifically against the Vietnam War. One long-standing American pacifist group is the War Resisters League (WRL). Founded during World War I, the WRL has led protest movements, has promoted secular pacifism, and has been a leader in promulgating draft resistance during most U.S. military engagements. The height of its influence was during the Vietnam War, when its members led many acts of civil disobedience. Other pacifists groups have religious foundations. For instance, American Quakers are active in international movements for peace and were particularly involved during the Vietnam War. On the home front, Quakers visited members of congress and led protests against the war based on their pacifist religion.

In 1968, Phillip Berrigan, a Josephite priest, and his brother Daniel Berrigan, a Jesuit priest, brought religious pacifism to the forefront with a daring raid of draft board files in Cantonsville, Maryland, which they destroyed with chicken blood and napalm. The Berrigans and their accomplices acknowledged that their actions were illegal but felt that they were justified by a higher power that called for a more just and civilized society. The Berrigan trial began a nationwide movement of sympathy for the antiwar movement and inspired other religious pacifists to act, such as when a group of Wisconsin Catholics burned 10,000 files in a Selective Service office.

There was a significant faction for peace in South Vietnam as well. The Buddhists of the war-torn country were particularly active in promoting peace. From the outset of the war, Buddhists had suffered oppression from U.S.-supported governments such as that of Ngo Dinh Diem, a

member of the country's Catholic minority. Despite representing about 80 percent of the South Vietnamese people, the Buddhists were often forced to turn to protests to make their voices heard. Thich Nhat Hanh was one of the most influential Vietnamese Buddhist monks and was responsible for leading a movement known as engaged Buddhism, which encouraged his followers to combine traditional meditation with nonviolent but active forms of civil disobedience. He worked relentlessly to bring peace between North and South Vietnam and was eventually exiled from both regions for his efforts.

In both 1963 and 1966, the most strenuous objections to the war came to the attention of the global community in the Buddhist Crisis as protests took a radical turn. For example, in the summer of 1963, Thich Quang Duc, a Buddhist monk, set himself on fire on a crowded Saigon street. As pacifists, the Buddhists made a significant impact on the war. Because the anticommunist regime in Saigon was never able to earn the complete support of the Buddhist majority, many historians have argued that the war was doomed from the outset. The plight of the Buddhists was well publicized in the United States and caused many Americans to take antiwar stances.

Antinuclear Weaponry Movement

The antinuclear weaponry movement has been a worldwide movement opposed to the development, testing, deployment, and use of nuclear

NUCLEAR ARMS RACE, 1945 – 1985

➤ STRONTIUM 90 IN BREAST MILK AND TEETH

“Your Children’s Teeth Contain Strontium-90,” proclaimed an advertisement taken out by the Dentists for SANE in the *New York Times* on April 7, 1963. The dentists’ group was affiliated with the lead antinuclear weaponry group of the day, SANE (the National Committee for a Sane Nuclear Policy). The ad declared that the teeth and bones of all of the children, indeed of all of the people in the world, contained the radioactive isotope strontium 90 as a result of the fallout from H-bomb tests being conducted by the United States and the Soviet Union. SANE and its affiliated groups were advocating for a treaty banning the atmospheric testing of nuclear weapons.

This ad was part of a series of ads that SANE had taken out that emphasized the dangers to public health posed not by nuclear war but by the testing of nuclear weapons. Fallout from nuclear weapon tests had been traced to areas far from the test sites themselves, and news stories had warned that traces of radioactive fallout had been detected in milk worldwide as well as in children’s teeth. Such efforts were a factor in the Partial Test Ban Treaty of 1963, which banned nuclear weapon tests in the atmosphere.

—Robert A. Jacobs

weapons as tools of war by any government. Some of these groups have worked to halt the spread of nuclear weapon technology and the growth of weapon stockpiles, while other groups have sought to eliminate such weapons from the arsenals of all nations.

Within mere months of the nuclear bombing of Hiroshima and Nagasaki, there were several organized antinuclear weapon groups. Among the most public and vociferous of the early movements were the antinuclear efforts of scientists, many of whom had worked on the Manhattan Project on the construction of the first bombs. These groups, known collectively as the scientists’ movement, worked diligently to educate people about the true dangers of nuclear weapons. They advocated for civilian as opposed to military control of atomic energy in the United States, which was achieved with Congress’s creation of the Atomic Energy Commission; they

also advocated for a world government to reduce the risk of nuclear warfare between nations. In 1945, members of the scientists’ movement created the magazine *Bulletin of the Atomic Scientists*, which published broadly on nuclear issues along with the Doomsday Clock, which the bulletin first featured in 1947. This is a visual representation of the level of nuclear tensions between the nations of the earth displayed in the format of a clock face showing how many minutes were left until midnight, with midnight representing nuclear war.

The scientists’ movement and other early antinuclear weaponry groups fell apart once the Soviet Union developed nuclear weapons in late 1949. Members of these early groups became the targets of the anticommunist fervor of the early 1950s, and their organizations were labeled communist front organizations. But in response to the development of thermonuclear weapons in the mid-1950s and the increased number of atmospheric nuclear weapon tests of the late 1950s, new groups dedicated to the abolition of nuclear weapons began to spring up.

This second wave of antinuclear weaponry protests was triggered by fears generated from the release of large quantities of radioactive particles from nuclear weapon testing. The Castle-Bravo test of the first deliverable hydrogen bomb in March 1954 produced radioactive fallout that contaminated hundreds of Pacific islanders and the crew of a Japanese fishing boat even though they were located well over 100 miles from ground zero. All of these people became sick from radiation poisoning, and eventually one of the Japanese fishermen died from radiation sickness. In the next several years, radioactive fallout from H-bomb tests were detected in many parts of the world, leading to widespread fears of contamination from testing separate from the fear of nuclear war itself.

Among the most important of the new antinuclear weaponry groups was the National Committee for a Sane Nuclear Policy (SANE), which took out a series of high-profile advertisements that dramatically raised awareness of the risks of fallout from weapon testing. SANE and other antinuclear groups helped to compel governments that possessed nuclear weapons to sign the Test Ban Treaty in 1963 that outlawed the testing of

weapons in the atmosphere. As the tests went underground, so too did public awareness of nuclear weapon testing itself, replaced in part by concerns about the conventional war being fought in Vietnam.

The third significant wave of antinuclear weaponry protests began in the early 1980s partly in response to a renewed round of nuclear brinksmanship from the administration of U.S. president Ronald Reagan. The worldwide Nuclear Freeze movement grew suddenly during 1980–1982 and included people from dozens of countries, generating some of the largest public protests ever held. These protestors demanded a freeze in the testing, production, and deployment of new nuclear weapons on the part of all nations that possessed nuclear weapons. In June 1982, more than 1 million people marched through New York's Central Park in support of the freeze, the largest protest ever held in U.S. history. Many more protested the deployment of new weapons in Western Europe to counter the superior numbers of Soviet ground troops in Eastern Europe. The fall of the Soviet Union in 1989 and the subsequent end of the Cold War marked the end of this most recent round of antinuclear weapon protests.

While previously the focus of antinuclear weaponry protests was centered on the threat of nuclear war posed by the Cold War between the United States and the Soviet Union, the post-Cold War focus has been on the problems of nuclear weapon proliferation. The acquisition of nuclear weapons by a number of smaller countries and the black market in nuclear technology have created a new dynamic that is likely to become the primary concern of any future protest movements.

Antiwar in Art, Literature, and Film

Wars never fail to elicit extreme reactions from those societies that are affected by them. During the twentieth century, as technology made wide-scale slaughter easier, antiwar messages became increasingly common worldwide in art, literature, and film.

Examples of visual art that revealed the atrocities and anguish that accompanied modern warfare became prevalent during World War I, particularly in the work of German artists George Grosz and Otto Dix.

Tom Cruise in *Born on the Fourth of July*, an Oliver Stone film based on the memoirs of Ron Kovic, a disabled Vietnam War veteran who became an antiwar activist, disenchanted with U.S. aims in Vietnam. (Universal/The Kobal Collection/Roland Neveu)

Antiwar literature in the form of poetry, short stories, and novels also became pronounced during World War I. *All Quiet on the Western Front* (first published in 1929 and produced as a film in 1930), German author Erich Remarque's story of a young soldier's depressing experience, made such a strong antiwar statement that the German government banned it.

Although the motivations behind the fighting of World War II were considered moral and just by many, even the so-called good war produced antiwar sentiment. The 1946 film *The Best Years of Our Lives* presented the troubles that former soldiers had in reacclimating to civilian life. John Hersey's 1946 book *Hiroshima* was one of the first to look at the horrific effects of the use of atomic bombs on Japan. Hersey's powerful work examines how the lives of six different people were altered by the bombing. Alain Resnais's 1955 documentary *Night and Fog* depicts the horrors of the Holocaust, with disturbing images of the deserted concentration camps contrasted with wartime footage.

Even in the 1950s before the United States had been deeply drawn into the quagmire, Graham Greene's *The Quiet American* (1955) predicted that American involvement in Southeast Asia would have disastrous consequences.

During the 1960s, the Vietnam War inspired a new generation of artists to use their craft to speak out against war. It also led to a rethinking of earlier wars. Joseph Heller's novel *Catch-22* (1961) is a fictionalized account that brought to light the confusion, guilt, corruption, and systematized irrationality that accompanied World War II. Kurt Vonnegut's *Slaughterhouse-Five* (1969) used satire and irony to convey the cruelty of war, particularly the Allied firebombing of Dresden during World War II. Thomas Berger's *Little Big Man* (1964) refashioned the usual heroic narrative of the conquest of the American West.

Specifically addressing the U.S. war in Vietnam, Antonio Frasconi's woodcuts depicted the massive U.S. bombings against North Vietnam, and the popular American artist Jasper Johns deviated from his apolitical yet iconic depictions of American flags with his *Moratorium* print. In this work, Johns departed from his traditional

red, white, and blue flag and instead painted a toxic flag, with the acid green background serving as a symbol of the poison of war that had spread across the nation. Of course, there were many other symbols of protest such as the peace symbol, which began as a symbol of the anti-nuclear movement of the 1950s, as well as posters depicting the white dove of peace. One popular poster, designed by Lorraine Schneider, declared that "War is not healthy for children and other living things."

Journalists began to write about their own experiences in Vietnam while maintaining an objective, factual depiction. Michael Herr's *Dispatches* (1977) offers a vivid portrayal of an American soldier's devastating experiences during the Vietnam War.

Tim O'Brien used his own personal experiences as a soldier to make strong statements with his novel *Going After Cacciato* (1978) and nonfiction works such as *If I Die in a Combat Zone* (1973) and the later novel *The Things They Carried* (1990). Bobbie Ann Mason's *In Country* (1985) is an emotional fictional account of characters who had their lives drastically altered by the war.

The Vietnam War also became a platform for many filmmakers to express their views on the horrors of modern war. Oliver Stone's films include indictments from the soldier's point of view, particularly in *Born on the Fourth of July* (1989) and *Platoon* (1986). Francis Ford Coppola's *Apocalypse Now* (1979) portrayed Vietnam as a hallucinatory experience. Along with antiwar art and literature, films have played an important role in expressing political and humanitarian views against war.

War Memorials since 1945

War memorials, particularly those of World War II, exist in many countries that were directly affected by armed conflict, military and civilian casualties, and the destruction of cities and infrastructure. Such memorials, in the form of museums, monuments, parks, and former concentration and death camps turned tourist destinations, have a considerable historical value often affected by contemporary politics related to public memory. How people choose to remember the past, as filtered through contemporary political and social realities, can determine how such war memorials function in bolstering either a semimythic collective memory or a less ideologically embellished and thus more accurate commemoration. Yet ideology—or a shared set of values and assumptions—inevitably colors all such displays.

In the aftermath of World War II in most every nation involved in the war, war memorials were erected to commemorate the dead, emphasizing their struggle against insurmountable odds or their status as victims caught in a situation beyond their control. The postwar divisions of Europe created an ideological divide that relegated most of Eastern Europe to the economic and political domination of the Soviet Union. Many of the war memorials in the communist Eastern Bloc constructed immediately after the war emphasized the solidarity of loyal socialists to the ideals of communism in the face of the fascist-capitalist invader, National Socialist Germany. In light of the impending Cold War, it was particularly important to emphasize the connection between fascism and capitalism given U.S. hegemony in Western Europe. This allowed the various communist governments in Eastern Europe to construct war memorials highlighting their subservience to communism during the so-called Great Patriotic War (World War II) while overlooking historical realities such as widespread collaboration with the enemy, particularly in Poland, the Baltic countries, and Hungary, or the

YASUKUNI SHRINE

(Matsukin)

Yasukuni Shrine was constructed in 1869 to commemorate Japanese war dead, initially of combatants who died for the Meiji emperor as part of the overthrow of the Tokugawa Shogunate. The names of over 2.4 million Japanese combatants of the nineteenth and twentieth centuries now are inscribed at Yasukuni Shrine in a “book of souls.” Believed to house the spirits of those commemorated, this Shinto shrine is particularly controversial because as of 1978, the names of 14 World War II war criminals were added. In subsequent decades, protests from the governments of the Koreas and China have followed Japanese prime ministers’ visits to the shrine.

—Fred Nadis

immediate postwar persecution and extermination of German refugees attempting to return westward into Germany (both East and West).

Memories of the Holocaust, the extermination of 6 million Jews under the National Socialist regime, took on different meanings in both the U.S.-dominated West and the Soviet-controlled East. In the democratic West, Holocaust memorials emphasized the destruction of European Jews at the hands of the Third Reich and its non-German collaborators. Museums, former camps, and monuments were established in various places in Europe, such as the Holocaust

► THE *ENOLA GAY* CONTROVERSY— U.S. MEMORY OF HIROSHIMA

As part of an exhibit at the Smithsonian Institution in 1994 commemorating the 50th anniversary of the atomic bombing of Hiroshima, the planned display of the fuselage of the bomber *Enola Gay*, used to drop the atomic bomb, ignited a national controversy. The exhibit “The Crossroads: The End of World War II, the Atomic Bomb and the Cold War” was prepared by the Smithsonian’s National Air and Space Museum and centered on a restored version of *Enola Gay*. However, various critics, particularly U.S. veterans’ groups such as the American Legion and the Air Force Association, alleged that the exhibit and its planned accompanying text focused only on the casualties caused by the bombing and not on the motives for the bombing (i.e., President Harry S. Truman’s assertion that the bombing would avoid massive American casualties from a land invasion of mainland Japan) or its role in ending the war.

The *Enola Gay* exhibit brought to national attention various academic and political issues directly related to interpretations of U.S. motives for the atomic bombing of Japanese cities. It became the center of political attention in Washington, when some Republican lawmakers threatened to cut off funding to the Smithsonian if the exhibit was not revised to meet the specifications of veterans’ groups. Academic historians and civil liberties organizations urged the Smithsonian to maintain the exhibit and not to falter amid such threats. Many attempts were made to revise the exhibit to meet the demands of the infuriated interest groups, achieving little to satisfy either side. The original director of the National Air and Space Museum, Martin Harwit, resigned a month before the bomber was finally displayed on June 28, 1995, with an exhibit emphasizing the *Enola Gay*’s role in ending World War II.

—Abraham O. Mendoza

memorial (Mémorial de la Shoah) in Paris, the Dachau concentration camp in Germany, and the Anne Frank House in the Netherlands, to commemorate the Jewish genocide and to serve as a reminder of genocide in our own time. In the socialist East, memorials that should have been associated with the Jewish people, such as

various Warsaw memorials in Poland and the Buchenwald concentration camp in the former East Germany, instead were associated with the suffering of loyal communists at the hands of fascism. Ethnicity and nationality were overlooked as factors in commemoration, with Jews recognized as Poles particularly in the memorial at Auschwitz (in Poland), completely evading the realities of Polish collaboration and leading many critics in the West to assume that this approach fulfilled ideological aims. In contrast, the newly created State of Israel (1948) commemorated the Holocaust in various museums and monuments, particularly Yad Vashem in Jerusalem, leading some critics to claim that such commemorative exhibitions were created to justify the creation of the Israeli state in Jewish collective memory.

In the portrayal of various war memorials in the former belligerent countries of World War II, the home country is generally depicted as a victim of war rather than as an aggressor, glossing over history to fit current domestic politics. In particular, Germans (both East and West) paint their past as victims of both the Nazis and the Allies in their memorials commemorating the catastrophic U.S. and British aerial bombings of Dresden and in the creation of the mythology of the so-called Good Germans (e.g., Klaus von Stauffenberg and the July Plot, Sophie Scholl and the White Rose movement). Such tactics completely disregard the role of a considerable German plurality during World War II in enacting National Socialist policies. In a similar vein, Japan’s memories of Hiroshima and Nagasaki often have been used to highlight the controversial American use of the atomic bomb while overlooking the role of the Japanese populace in supporting wars of aggression in Southeast Asia, China, and the Pacific. In particular, the Yasukuni Shrine in Japan, where a number of convicted World War II war criminals are interred, has been regularly visited by Japanese politicians, leading to protests in China and North and South Korea. Much like German memorials, this emphasis causes much consternation among the descendants of former conquered enemies and victims.

Another type of war memorial, purposefully lacking in ideological and political sentiment, allows the observer to interpret it from his or

her own perspective. War memorials, such as the Pearl Harbor National Monument in Hawaii and the Vietnam War Memorial in Washington, D.C., are attempts to commemorate events with a minimum of ideological baggage rather than create mythological constructs to influence collective memory. Such displays, with a minimum of context cues, allow people from different points of view to commemorate and view such an exhibit with their own interpretation of the event under observation. The Vietnam War Memorial, characterized by the inscriptions of the names of the U.S. war dead on two black granite walls, allows the observer to commemorate the Vietnam War

from his or her own personal perspective. However, these war memorials are still scrutinized by some critics and veterans groups as disrespectful or negligent of the troops' efforts.

Thought and Religion

The changing reality of life after World War II has had a dramatic impact on theologians, philosophers, and established worldviews. The period from 1945 to the present, as reflected in thought and religion, can usefully be dubbed the age of posts. Depending on who is making the list, these posts for thought and religion might include postwar, post-Holocaust, postcolonial, and postmodern. These terms indicate radical challenges to ruling belief systems. From the perspective of the early twenty-first century, the brutal events of the preceding century (including the use of atomic weapons and the death camps of the Holocaust) revealed the limits of the simple faith in scientific progress and rationality that was common in the West since the period of the Enlightenment. Throughout his work, Karl Marx argued that thought, and for that matter religion, follows the economic base. Peoples and governments rationalize their economic and political systems in terms of a shared ideology. In the postwar period, cracks began to appear in dominant ideologies (this includes both the communist and capitalist worlds). Since 1945, in addition to a growing distrust with the notion of progress, the economic transformation connected to increasing globalization has forced critiques of Eurocentric or Western-centric assumptions and hierarchies in thought. This has sharpened some cultural divides and ideological conflicts yet also offers greater hopes for a widening ecumenism, that is, efforts to seek unity across significant divides.

The atrocities of World War II gave a new impetus to an ecumenical movement. Reactions to war atrocities had a major impact on thought and religion, as people of conscience reflected on the Holocaust, in which the Nazis and their collaborators, with little opposition, slaughtered 6 million Jews and another 2 million perceived enemies including non-Jewish Poles, Roma-Sinti (Gypsies), disabled people, and homosexuals. The Holocaust revealed the ultimate amorality of the ideals of efficiency and rationality as well as the bankruptcy of the racial and ethnic hierarchies embedded in the Western concepts of progress and modernization. In a conscious effort to promote ecumenism—that is, an acceptance of religious pluralism and outreach between different denominations—the World Council of Churches was formed in 1948 with a meeting in Amsterdam. The aftermath of World War II and the Holocaust also played a role in prompting the Catholic Church's liberal reforms during

Vatican II in the early 1960s; implicit in Vatican II was a decision to move beyond the Catholic Church's earlier rejections of religious pluralism and to further notions of tolerance and ecumenism. In a general way it can be said that all of the major world religions underwent a similar shift to liberalization, as social activism and a concern with poverty and social equality began to inflect mainline religious services in the developed and developing world in the 1950s and 1960s. The African American church had a major role in the U.S. civil rights movement of the 1950s and 1960s, affirming the connection between religion and social activism; protests against the U.S. role in the Vietnam War also galvanized the liberal clergy in the United States; in ensuing decades, Catholic priests in Latin America promoted the cause of liberation theology to promote social equality and combat poverty and its ills.

One of the major surprises to secularists and believers in the idea of progress has been the religious ferment of the postwar period. Despite the high hopes for the secularist state (one in which religion has no direct structural role) on both sides of the Cold War divide—including an active suppression of religion in much of the Communist Bloc—religion did not wither away. The Cold War nuclear arms race, in which nuclear annihilation could at any moment be imminent, encouraged a millennialist attitude that the end was near. Such fears aided, for example, the mass Christian revivals of the 1950s, typified by Billy Graham's crusades in the United States and Britain. In the communist world, a newly suppressed Church became a powerful force of opposition to central authority, as particularly seen in Poland after the harsh suppression of clergy. While the founders of the State of Israel by and large were secular socialists, ultra-Orthodox Jews, seeing in secular Zionist a fulfillment of a narrative of religious redemption, consistently urged the establishment of a state religion and grew to become a powerful political force, represented in the Knesset, the Israeli parliament. In the developing world, the last few decades of the twentieth century showed the consistent growth of Christian evangelism, particularly of Pentecostalism in

Latin America and Africa. Adherents to Islam have also increased, as the secularist vision of authoritarian states, such as that under the shah of Iran, were deemed social catastrophes, and as a global labor market stimulated the growth of large diaspora communities for which religious identity provides cohesion. Religious fundamentalism as a political force, whether channeled through nonstate revolutionary groups or via electoral politics, has become a part of the fabric of politics in the

Religious fundamentalism as a political force, whether channeled through nonstate revolutionary groups or via electoral politics, has become a part of the fabric of politics in the United States, Israel, many Islamic majority countries, South Asia, and elsewhere.

United States, Israel, many Islamic majority countries, South Asia, and elsewhere. Clearly, mainstream religions have not withered either. All the major religions have grown, so that as of 2009 Christianity, with its 2 billion adherents, and Islam, with over 1.25 billion adherents, constituted more than half of the world's population.

As European powers withdrew from former colonies in the postwar period, some indigenous leaders placed their hopes in the secular state on the Western model (alongside the possibilities of modernization and development), but many also sought to shape institutions that preserved and valorized traditional culture. Authors such as Frantz Fanon, and later Edward Said, argued that a view of cultural superiority and hierarchy was enmeshed in European language and thought. Such assumptions were to be overturned. Postcolonialist intellectuals did not necessarily reject the modern but rather embraced a hybrid identity as well as new syncretic (synthesized from varied sources) forms of governance, culture, and even religious worship. From such a point of view, secularism could be painted as a cohort of Western imperialism. Mao Zedong, as leader of the People's Republic of China, supported a radical anti-imperialist vision for the developing world that also encouraged a harsh rejection of Western support. For Mao it was not so much modernity but imperialism that had to be rejected. Countries with Islamic majorities such as Turkey early in the twentieth century, and Iran in mid-century, had embarked on modernization projects, yet the Iranian Revolution indicated a strong faction that rejected Western domination and Western values and that largely approved a return to the guiding principles of Islam and a theocratic state. Secularists and Islamists still are engaged in a standoff in these countries, with Islamists generally rejecting local nationalist identities—and for that matter, the bland unitary identity implied in globalization—while preferring the dream of an *ummah*, or united Islam. The breakup of colonialism, as well as of the Soviet Union, has led many peoples to link nationalist dreams with religious affiliations. A prime example would be the conflicted relationship in postcolonial South Asia among Hindu, Muslim, and Sikh nationalists.

The term “postmodern” is a catch-all that attempts to map many of the conditions discussed above for the post-1945 period. First, it marks a rejection of modernism, such as the sleek geometric style in prewar architecture that was perhaps the apotheosis of Enlightenment ideals of rationalism. Second, it marks an attempt to decode and reject the cultural hierarchies embedded in literature, language, and culture. These hierarchies might reflect not only cultural imperialism but also unstated sexist, racist, or even speciesist assumptions. And perhaps most importantly, postmodernism revolves around a diagnosis of the economic condition that Frederic Jameson termed late capitalism. Late capitalism, which might also be termed high consumerism, encourages an advertising-soaked culture in which signs and images gain dominance over text and logic. The postmodern analysis of late capitalism also dovetails with the acceleration of globalization, that is, the spread of consumer culture concentrated in global cities. Postmodern thought acknowledges the impact of global migrations, growing diasporic communities, and the hybridization of culture in which regional traditions and norms are mixed and dissolved. Literary critics have spoken of de-centered texts, and postmodernists also have argued for a de-centered social landscape in which cultural authority is up for grabs. Eurocentrism is no longer a hidden assumption but instead is more easily revealed as a

slight absurdity in a global age. For some, postmodernism implies a relativism that moves past the ethic of ecumenism to an embrace of the irrational—or at least extreme skepticism. Meaning ultimately cannot be grounded. Anyone with a Web site can reach out to a global audience, and, potentially, initiate a new religion. A culture of signs encourages a neoprimitivism that Marshall McLuhan first diagnosed when he spoke of the new tribalism of media culture. And indeed, what are termed New Religious Movements, whether decked out with archaic or science fiction trappings, have flourished since the dropping of the atomic bomb as old myths are repackaged and spread anew in forms varying from shaman retreat seminars to neopaganism or Scientology. Conspiracy theories have also proliferated as traditional centers of cultural authority (including faith in scientific authority) are questioned and new modes of communications such as the Internet and cell phone text messaging systems allow rumors to spread and gather momentum.

While what might be termed the postmodern era has not yet come to an end, certainly the vision of meaning as an exile in an endless hall of mirrors has limited appeal. Late capitalism with its luxury and fog of deception may be giving way in a new age of limits in which both global warming and economic downturn demand a more grounded ethical vision.

—Fred Nadis

■ Introduction: Major World Religions

Recent developments in Buddhism, Christianity, Judaism, Islam, and Hinduism have collectively assembled the foundation for most spiritual experience in the twenty-first century. While many new converts were made to these major world religions, alternative religions have also grown.

Shortly after World War II, Buddhism in China, Tibet, and Cambodia suffered suppression under communism. When Chinese Buddhism refused to die upon the 1949 institution of the People's Republic, the government engineered violent attacks on Buddhist temples and leaders during 1966–1976. This action represented a continuation of communist China's suppression of Buddhism after its 1959 invasion of Tibet in which monasteries were looted, libraries were burned, over one million believers were martyred, and the current Dalai Lama, Tenzin Gyatso (b. 1935) was forced into exile. Likewise, between 1975 and 1979 the Khmer Rouge launched

a systematic decimation of Cambodian Buddhism. But these losses have been more than counterbalanced by Buddhism's significant growth in the non-Asian world. Daisetz Teitaro Suzuki (1870–1966) effectively transmitted Buddhism in general and Zen in particular to a generation of Westerners through over 30 volumes in English.

The Roman Catholic Church experienced internal revitalization and external reconciliation with other Christian groups at Vatican II (1962–1965), called by Pope John XXIII (r. 1958–1963). Championing *aggiornamento* (renewal or bringing up to date), Vatican II substituted the vernacular for Latin in the Mass, eliminated the Index of Prohibited Books, sanctioned new translations of the Bible, and authorized lay women and men to serve as teachers, Eucharistic ministers, and altar attendants. Not only did Pope Paul VI (r. 1963–1978) and Ecumenical Patriarch Athenagoras I (r. 1948–1972) revoke the 1054 mutual excommunication between Catholics and Eastern

Orthodox, but the council deemed Protestants as separated brethren no longer to be regarded as heretics.

Following the 1948 establishment of the World Council of Churches, newly allied Protestants sustained an ecumenical spirit through the Evangelicals and Catholics Together movement (started in 1994) and the 1999 Joint Statement on Justification between the Lutheran World Federation and the Catholic Church. In some cases denominations rejoined to heal old schisms, while in other cases struggles between theologically liberal church leaders and more conservative or orthodox leaders led to significant separations into new church bodies. Even the Roman Catholic Church suffered losses in membership due to the spread of secularism.

In the West, secularization has triggered the decline of mainline denominations. These denominations have adopted liberal theologies that are secularized versions of traditional beliefs, have abandoned traditional convert-making missions, and have become essentially social service agencies. Secularization in the West has not meant the abandonment of religion for atheism except for relatively small numbers of people. The most common response to the abandonment of traditional Christianity has been the adoption of some form of spirituality. The alternative religions of today can be categorized as new religions or as the return of the religions of native peoples. Neopaganism, for example, may include practices and beliefs derived from the religions of native peoples, including a revived interest in shamanism.

The most significant Christian increases are transpiring outside the Western world, as the Pentecostal-Charismatic movement sweeps through Latin America, Africa, and Asia. In addition, Orthodox Christianity moved beyond its ancient heartland of Eastern and Southern Europe to assume a significant presence in the Americas and in Australia through the migration of numerous Greek and Slavic immigrants. Today Christianity is no longer a North American and European religion but instead is a truly global faith, with 1.2 billion non-Western Christians compared to .8 billion Western ones. Many non-Western churches see Europe and North America as mission fields. As immigrants from Asia,

Latin America, and Africa, both legal and illegal, have moved into Western Europe and North America, they have brought their strongly held faith and have become communities of spiritual renewal to either compete with or to renew mainline Christianity.

Largely as a response to the Holocaust, the United Nations partitioned the formerly British-governed Palestine into Jewish and Arab sectors, thereby creating the modern nation-state of Israel in 1948. Several diverse schools of thought thrive in contemporary Judaism. Most traditional is Orthodox Judaism, holding strictly to the Decalogue plus 613 additional mitzvot, or commandments, in the Torah. By contrast, Reform Jews regard most mitzvot as outdated and instead conceive the essence of Judaism as an ethical monotheism harmonious with progress. Mediating between the Orthodox and Reform branches, Conservative Judaism preserves traditional practices but reinterprets Jewish law in view of modernity and historical criticism.

Over the past 30 years Western academics have observed the trend of Islamic revival or resurgent Islam in Africa, the Middle East, and North America. Although the events of September 11, 2001, evoked a clash of civilizations in Western consciousness, two pacifying dynamics are frequently overlooked. First, many Muslim leaders worldwide sense the need to modernize Islam by allowing lay Muslims to interpret the Quran for themselves in ways that take into account twenty-first-century cultural circumstances. Second, realizing that extremists frame current sociopolitical problems in theological terms, Muslim moderates have exhorted Western governments to undermine extremist solutions by proactively remedying past and present injustices against Muslims in Palestine, Iraq, Chechnya, Algeria, and Bosnia. The tension between Islamism and moderate Islam can best be seen in the Shia nation-state of Iran, where a largely tolerant population has found itself at odds with antimodern leadership since the ascendancy of Ayatollah Khomeini (1902–1989) in the 1979 Islamic Revolution.

It should be noted that religious extremism is not unique to Islam but can be found in most if not all religions. By “extremism” means the attempt to live out the principles of the religion in an absolute manner that may include in the case

of Christians a refusal to use the means of medical science and instead depend upon faith healing for the treatment of a disease or injury. Other forms of extremism include the use of violence to advance religious beliefs, which has been seized upon by fringe groups in Judaism, Christianity, Islam, Hinduism, Sikhism, and other religions.

Mohandas (Mahatma) Gandhi (1869–1948) attempted to synthesize Hindu spirituality with politics as he spearheaded the 1947 victory of Indian independence movements in breaking from British colonial rule. At the center of this effort was Gandhi's concept of truth grasping, derived from karma-yoga and the Sermon on the Mount, according to which spiritual integrity and discipline in individual life proved indispensable for securing communal moral victories in the political arena. Accordingly, Gandhi championed nonviolent resistance against imperial rule and advocated the dissolution of caste restrictions against the *barijans* (untouchables), advances for the latter of which are now enshrined in an Indian democratic constitution. Despite his successful leadership, Gandhi was assassinated by a Hindu extremist.

Finally, India's inheritance of the English language has enabled it to spread Hindu teachings in English rather than in the less widely spoken Hindi or in the classical language of Sanskrit. Born in sixteenth-century India with roots in Hinduism and Islam, Sikhism has spread from its native Punjab to most major Western cities and now claims nearly 19 million followers.

The religions of African and American indigenous groups continue to exist and effectively allow tribal histories and memories of the ancestors to exert a powerful impact on the present. In some cases indigenous religions have increased with population growth.

Hinduism since 1945

With roughly 900 million adherents worldwide, Hinduism has the third largest following among the world's religions (the two largest being Christianity and Islam, respectively). Hinduism is also the oldest of today's major religions, with a scriptural tradition dating to roughly 1500 BCE and some beliefs and practices possibly being derived from the Indus Valley civilization (ca. 2600–1900 BCE).

The vast majority of Hindus live in India and its neighboring countries in South Asia. Most Hindus are of South Asian ethnic descent, though in the modern period, non-South Asian practitioners of Hinduism have also emerged in North America and Europe due to the activities of spiritual teachers who have spread Hindu ideas and practices to the West. The first such spiritual teacher to have a major impact was Swami Vivekananda, whose address to the Parliament of World Religions in Chicago in 1893 is regarded as a watershed event in which Hinduism was popularized in the West for the first time.

Having no single founding figure or centralized institution, such as a church, to define correct belief and practice, Hinduism is a highly internally diversified and loosely organized tradition. In fact, Hinduism is better defined as a family of related traditions, united under the umbrella term "Hinduism," than as a singular tradition. The diversity of views and practices coexisting under this term rivals that of the world's major religions, with some Hindus believing in an impersonal ultimate reality (not unlike Buddhists and Taoists), others practicing devotion to a personal deity (not unlike Jews, Christians, and Muslims), and still others having no religious belief but living their lives according to Hindu cultural norms and societal expectations.

Bearing this internal diversity in mind, though, it is possible to locate widely held beliefs and practices that most Hindus share. Most Hindus believe in rebirth, or reincarnation, ac-

cording to which the souls of living beings are reborn in another form after death. This view is described in the widely revered Hindu scripture the *Bhagavad Gita* (Song of the Lord) as being akin to someone exchanging a set of old worn-out clothes for a new set. The type of body that the soul inhabits is determined by karma, a law of cause and effect that could be compared to Newton's Third Law of Motion: "For every action, there is an equal and opposite reaction." But karma applies not only in the realm of physics but also in the realm of morality and spirituality. Life can be seen as a school in which one is gradually learning right from wrong, through trial and error, and moving lifetime after lifetime toward the ultimate goal: *moksha*, or liberation from the cycle of birth, death, and rebirth.

The ways of attaining *moksha* and the ways in which *moksha* is conceived vary in different Hindu traditions. The Advaita Vedanta tradition views *moksha* as a matter of realizing the true nature of existence: that the self is ultimately identical to Brahman, the ultimate reality. In this view, our existence in the realm of rebirth is like a dream from which we are seeking to awaken. The Vaishnava traditions, in contrast, view *moksha* as a gift from God with whom one needs to cultivate a relationship of devotion, or *bhakti*. These views and others can all find support in the vast and greatly varied body of sacred texts on which the Hindu traditions are based, beginning with the *Vedas* (which most scholars date to between 1500 and 1000 BCE, though Hindu traditions hold them to be much older than this) and continuing through the *Upanishads* (ca. 600 to 200 BCE), the *Ramayana* and *Mahabharata* (ca. 300 BCE to 300 CE), the *Puranas* (ca. 300 to 600 CE), and numerous other philosophical and legal writings, or *shastras*.

Another feature of Hinduism is the social practice of *varna* (caste), a hereditary system of occupations that ranks different tasks in a hierarchy of purity, with Brahmins, the priestly caste, at the top and various menial tasks, considered unclean, at the bottom.

In the modern period, caste has become highly controversial in Hindu society, in some ways analogous to the issue of race in North America and Europe. While caste is still practiced in a highly conservative form in rural India,

Hindu reformers have sought either to divest it of the prejudicial attitudes with which it has been associated (this was the approach, for example, of Mahatma Gandhi) or to do away with it altogether (the approach of B. R. Ambedkar, the author of the Indian constitution).

Finally, the modern Hindu tradition has been characterized by tension between a universalist and pluralistic vision of Hinduism—embodied by such figures as Vivekananda and Gandhi—and Hindu nationalism, which identifies Hinduism exclusively with Indian nationality and ethnicity.

Buddhism since 1945

Buddhism in the late modern period has experienced unprecedented opportunities for worldwide growth and serious challenges to its traditional forms of thought and practice. Prior to 1945, many Asian societies that were home to the Buddhist religion were under European colonial rule. Asian Buddhists and European colonialists and travelers emerged from these encounters profoundly changed, with Buddhists more keenly aware of their religion as something comparable to, yet different from, other religions such as Christianity. Europeans, and then later during World War II American military personnel, were exposed to Buddhist ideas, practices, and art, leading some of them to take a particular interest in the religion. These encounters would pave the way for the global spread of Buddhism and its practitioners, a phenomenon that accelerated in terms of pace and intensity after 1945.

A distinctly new form of Modern Buddhism had already begun to take shape starting in the latter part of the nineteenth century. This Modern Buddhism tended to be represented first and foremost as a system of ethical philosophy that excluded many of the traditional rituals found in the everyday lives of Asian Buddhists. Having redefined Buddhism as a supremely ethical and

➤ DALAI LAMA

The Dalai Lama is arguably the most recognizable and influential Buddhist living today. Born on July 6, 1935, in northeastern Tibet, Tenzin Gyatso was identified as the fourteenth reincarnation of the leader of the Gelug school of Tibetan Buddhist monks and was installed as the spiritual leader of Tibet in 1940. The title “Dalai Lama” translates as “Ocean (of Wisdom) Teacher,” and a Mongol ruler who converted to Buddhism in 1578 first bestowed it to the third successor of the monk Tsongkhapa, who founded the Gelug lineage. Ever since, the leader of the Gelug School has been called the Dalai Lama. The Fifth Dalai Lama (1617–1682) employed Mongol troops to defeat his enemies and consolidate his political power, effectively becoming the ruling viceroy over all Tibet. Each successive Dalai Lama was able to retain control over Tibet with the patronage and support of the Chinese well into the twentieth century, although this relationship ultimately compromised Tibet’s independent status after being annexed by the People’s Republic of China in 1959. In that same year, the current Dalai Lama was forced into exile and resettled in India along with tens of thousands of Tibetan refugees.

Currently, the Fourteenth Dalai Lama travels the world to advocate for Tibetan self-determination and the preservation of Tibetan culture. He is the acknowledged and beloved head of the Tibetan exile community, a Nobel Peace Prize winner, and a source of consternation for the government of China, which would like to quell Tibetan aspirations for independence. He is also a leading spokesperson for a modern form of Buddhism that highlights the tradition’s ethical foundations and compatibility with science. The Dalai Lama remains at the center of efforts to find a solution to the so-called Tibet Question that would preserve Tibetan Buddhism and culture within a political framework acceptable to China.

—Stephen C. Berkwitz

rationalistic faith, twentieth-century Buddhists of both Asian and Western origins were at once able to fend off the critiques of idolatry and superstition made by non-Buddhists and to invest Buddhism with a kind of universality that freed it from particular constraints of time and place. These changes were the products of larger pro-

cesses of globalization. The increasing attraction of democratic ideals, capitalist market forces, scientific knowledge, Western models of development, and popular culture across the world since 1945 have caused a radical break in the ways that Buddhism and Buddhist identity have been traditionally practiced and understood.

This newer globalized form of Buddhism, heavily influenced by encounters with Western cultures and institutions, has emerged as a competitor to more local and traditional forms of the religion. While Modern Buddhism is more widespread and perhaps more well entrenched in Western cultures, most of the world’s Buddhist population continues to privilege traditional rituals of venerating Buddha images and relics, supporting and paying homage to monks and nuns, and earning and sharing merit from the performance of deeds thought to yield positive karmic fruits. Buddhist thought generally affirms that such practices are helpful in alleviating the suffering of beings who are not yet liberated from *samsara*, or the cycle of repeated birth and death. However, there are some in Buddhist cultures who denounce, or at least supplement, traditional ritual forms of the religion in favor of (or in combination with) more universalizing modern expressions of Buddhism.

The spread of Modern Buddhism and its concordant emphases on meditation, egalitarian social structures, and a nonsectarian vision of what it means to be Buddhist are arguably the definitive characteristics of postwar Buddhism as a whole. In the past several decades, meditation has become the paradigmatic Buddhist practice, and it has been taken up by more laypersons than ever before in home practice, sitting groups, and meditation retreats. The stress on meditation as a Buddhist practice that is no longer restricted to a select group of monks supports the idea that nirvana (the ultimate goal of liberation from suffering and rebirth) is an attainable goal for almost everyone. This notion, moreover, symbolizes in Modern Buddhism the transcendence of traditional religious hierarchies that privilege monks over laypersons. The practice of meditation, with its emphasis on experience over textual study and moral discipline, has allowed Buddhists to embrace more democratic and egalitarian models for their communities. At the same time, the de-

centralization of traditional religious authority—in the form of texts and monks—has led Modern Buddhists to dismiss the relevance of sectarian identities and selectively appropriate certain practices and ideas from a variety of Asian Buddhist traditions.

Although the expansion of knowledge about and interest in Buddhism since 1945 is largely seen as a positive development, there have been negative trends as well. Huge numbers of Buddhists have become the victims of religious and political persecutions since 1945, leading many to worry about the future of their religion. Buddhist monks have suffered at the hands of Chinese communists who took over Tibet in 1951, the Khmer Rouge genocide in Cambodia during the late 1970s, and the violent separatist Tamil Tigers in Sri Lanka since 1982, among others. Communism and Islamism have also directly led to the suppression and destruction of Buddhist institutions and monuments across Asia from time to time. Nevertheless, the survival and continued growth of Buddhism in the modern world seems assured, even if we do not yet know the long-term effects of modernity on the more traditional forms of the religion.

Islam since 1945

As of 2009, Islam remained the world's second most common religion, with at least 1.2 billion

adherents globally. Of these, nearly 75 percent identify themselves as Sunni, while the second-largest grouping, Shia Muslims, live predominately in Iran, Syria, and Lebanon. The Sunni-Shia division followed an early dispute over the rightful successor to Muhammad, Islam's founding prophet; in the contemporary world, this division also includes the acceptability of different schools of Islamic law and interpretation. All Muslims honor what are known as Islam's five pillars, which include *shahada*, the testimony of faith; *salah*, daily prayer; *zakah*, providing alms; *sawm*, the Ramadan fast; and the *hajj*, or pilgrimage to Mecca, expected of every Muslim at least once in their life.

At the end of World War II, most of the world's Muslims lived primarily in the Middle East, North Africa, Central Asia, South Asia, and Indonesia. The effects of global migration patterns, growing oil revenues, modern technology, and a high birthrate contributed to an Islamic religious revival and aided the global spread of Islam from these core regions to Europe and the Americas. The tug between modernism and anti-modernist sentiments—as well as the relationship between moderate and radicals within Islam, between Sunni and Shia Muslims (as well as Sufis in Pakistan), and the reflection of such fissures in politics and governance—have informed much of Islamic developments since 1945. While dramatic events of recent decades indicate the historical impact of violent Islamist groups, varying calls for reform are as common as calls for revival throughout the Muslim world.

As one approach to modernization, Islamic secularism was adapted, particularly in Sunni-dominated countries, and was implemented in the early twentieth century in Turkey and later in Arabic-speaking countries as nationalist parties (such as the Baath in Iraq and Syria) came into power. These parties often suppressed or discouraged Islamist fervor because it was viewed as a political threat. The aspirations of many nationalists and secularists included democratizing and modernizing the old autocratic Islamic societies to some extent. In the case of the new autocratic Baathist regimes, however, secularization and democracy did not go hand in hand. From 1945 until the Islamic Revolution in Iran in 1979, nationalists sought to order and govern Middle

Eastern states along a secularist course of modern development. In Turkey the secularism begun by Kemal Ataturk (1881–1938) continued, but like secularism elsewhere in Islamic countries, it was increasingly countered by growing Islamic revivals sponsored by the Shia revivals in Iran and the Sunni revival of faith and practice preached by the Wahhabi or by other strict Islamists.

Of significant importance to the revival and growth of Islam in the modern world was the enormous increase in birthrates for Muslims. Educational opportunities grew with the growth of oil wealth and the construction of schools. This was coupled with the spread of modern scientific medicine that saved the lives of millions. The growing population, endemic poverty, and numerous wars in the Middle East and North Africa created the push that led to widespread immigration. This was coupled with the pull of growing global prosperity that allowed emigrants from heavily Muslim countries to settle around the world, taking their faith with them. This resulted in new Muslim diasporic communities along with new mosques. Islamic centers developed in Europe, Oceania, and the Americas. In France, the Muslim population grew to a significant portion of the total population as immigrants arrived from former North African colonies, particularly Algeria. In Germany, large numbers of Turkish guest workers established families and flourishing diasporic communities in major cities.

While many of the new mosques in places such as the United States were often constructed by Muslims who preferred to live in a secular civil society, a growing number were constructed and staffed by traditionalist leaders from the Middle East. After the Balkan War that followed the collapse of the former Yugoslavia in the 1990s, Wahhabi money and preachers rebuilt mosques across Bosnia-Herzegovina and radicalized a portion of its population. Traditional and radical forms of Islam accelerated in importance following the Iranian Revolution of 1979 and the Taliban's seizure of power in Afghanistan in the 1990s. The more extreme variants of these supported the attacks on the United States on September 11, 2001. Others contributed to the establishment of Islamic courts in countries with large Muslim populations such as Canada and

Britain, courts that to some degree have allowed for arbitration and Sharia-based interpretations. Yet it should be stressed that even in the majority of Islamic countries (not including the Gulf nations), Sharia law generally only pertains to issues of family law and inheritance.

Women's rights movements that began in the West in the 1970s influenced women in Islamic countries to work against the patriarchal constraints of traditionalist Muslim society, creating, along with social democracy and human rights issues, a crucial thread in the discourse of Islamic reform. Such reformers emphasize the tradition within Islam of *ijtihad*, or the use of critical reasoning to challenge received opinion and interpretation. Islamic jurists are included in their ranks. Muslim feminists, who have ranged from secularist to traditionalist in viewpoint, have interpreted the Quran to illustrate that the Prophet Muhammad had supported better treatment for women in early Islam, and therefore his practice and words should be followed to allow for greater inclusion of women in Muslim society. Feminist organizations also operate in the face of much opposition and open rejection in countries such as Afghanistan. Other progressive Muslims have supported a range of causes and groups such as the Children's Rights Society in Iran and medical and social support for HIV-positive Muslims in Africa.

While episodes such as death threats sent to European newspapers for publishing cartoons that satirized images of Muhammad in 2005–2006 indicate a strong current of intolerance, Islam cannot be seen as a monolithic or even reactionary force. The doctrine of jihad (literally “to struggle or strive”), for example, has numerous interpretations that range from prescriptions for waging a violent holy war to an intense personal struggle to seek enlightenment and improvement as a society or an individual. Many interpreters of the Quran will insist that militant groups have misappropriated the term “jihad.” Moreover, interpretations of Islam by clerics and scholars that range from moderate modernist to progressive in position, including those of scholars such as Fazlur Rahman, Shabbir Akhtar, Mohammad Arkoun, and Abdolkarim Soroush, argue that Islam can and should support progressive approaches to gender equity and social

justice. Others insist that Islam is dynamic in nature and can adapt to secular civil societies while retaining traditions in the personal sphere and the Islamic community.

Catholicism since 1945

The social and political upheavals of the twentieth century affected the direction of Roman Catholicism after 1945. Catholic popes, bishops, and priests responded to some of the most important issues and events of the period, sometimes with hesitancy and other times with forthrightness. Catholics around the world experienced and participated in the world wars, the Cold War, ecumenical councils with Protestants and Eastern Orthodox clergy in unofficial capacities, international missions, and political movements. Catholics of all types struggled to negotiate between their Christian faith and their socioeconomic circumstances, between the global and local application of Catholicism in the world.

Millions of Roman Catholics fought in World War II. Millions more experienced the atrocities of war from the home front or concentration camps. After the war, national, political, and ideological loyalties continued to divide Catholics. The exposure of the Holocaust and the complicity of many Catholic leaders compelled some to reconsider the role of the Church in society. It was not until the 1990s that Catholic leaders, including Pope John Paul II, officially apologized for the direct or indirect involvement of the Church in the Holocaust.

> VATICAN II

In an effort to reorient the Roman Catholic Church so that its ministry would be more effective in reaching and serving people increasingly shaped by modernist secular culture, Pope John XXIII called for an ecumenical council of bishops on January 25, 1959. He intended for the council to improve the internal organization of the Church, the unity of all Christians, and the prospects for peace around the world. Cardinals, bishops, priests, and theologians met for a total of ten weeks during the autumn of 1962 through 1965. Members of Eastern Orthodox and Protestant denominations also came as invited observers.

Pope John XXIII died during the second year of the council and was later succeeded by Pope Paul VI. The council issued 16 documents ranging in topics from the sacred liturgy to ecumenism to religious freedom. Approximately 2,800 people acted as members of the council over the four-year period. Vatican II was the first council of its kind since the First Vatican Council of 1869–1870 but possibly the most ecumenical since the councils of the early Church.

Pope John XXIII described Vatican II as an *aggiornamento*, or an updating of the Church's active role in society. The council adjusted the manner in which Catholics participated in the sacrament of mass, as seen most evidently in the replacement of Latin with vernacular languages. The council also brought to light tensions between tradition and modernism within the Church over issues of ecclesiastical authority, lay involvement in the everyday life of the Church, the ordination of women, and the marriage of priests.

Since 1965, Catholics have attempted to interpret and implement the teachings of Vatican II. Debates over the messages of Vatican II continue at all levels of the Church.

—*Michael Pasquier*

One reason for the Catholic Church's lack of public attention to the Holocaust was its interest in the immediate threat of communism and the Soviet Union after World War II. Pope Pius XII warned against the rise of communism as early as 1945. Through the Catholic Action movement, the pope mobilized Italian Catholics to oppose the Communist Party in Italy. He also condemned

the communist regimes of Eastern Europe for the persecution of Catholics.

Pope John XXIII succeeded Pope Pius XII in 1958 and quickly moved to address the social ills that communists often attributed to Church-influenced societies. He considered it the duty of Catholics to disprove the Marxist critique of the Church as unaccountable to the plight of ordinary people. To do so, the pope called for an ecumenical council, known as the Second Vatican Council (1962–1965), in order to meet the challenges of modern society and particularly communism.

The debate over the proper interpretation and application of the Vatican II documents caused ideological rifts both inside and outside the Church. By the end of the 1960s, Pope Paul VI reaffirmed traditional Catholic teachings on marriage, contraception, and procreation in an effort to curb the influence of some of the more liberal promoters of Vatican II in Europe and North America. Gradually the European and American Catholic hierarchy moved toward a more conservative application of Vatican II as the reforms continued to be implemented during the pontificate of John Paul II (1978–2005). Yet despite the efforts of Rome, many lay Catholics as well as some members of the clergy and religious orders took positions that challenged official Church teachings.

Besides doctrinal issues, Pope John Paul II carried on the efforts of previous popes in opposition to communism. As the archbishop of Krakow in communist Poland, Pope John Paul II, known at the time as Carol Wojtyła, promoted Polish opposition to Marxist ideology and communist government policies. After his ordination as pope in 1978, John Paul II supported the Solidarity movement in Poland that contributed immensely to the demise of communism throughout Europe during the 1980s.

Catholicism took a somewhat different direction in Latin America, Asia, and Africa after Vatican II due in large part to the emergence of a theology of liberation. Building on the ideas of previous thinkers and activists, a Catholic layperson from Latin America named Gustavo Gutierrez brought to the attention of the Church the need for social justice among the poor and mar-

ginalized members of society during the 1960s and 1970s. The goal of liberation theology was to manifest social justice throughout the world. Many Catholics in Asia and Africa incorporated the message of liberation theology into their churches. Many Catholics in Europe and North America, however, identified Marxism with liberation theology, which led many Church leaders and theologians to question the legitimacy of the liberation movement.

In the period after Vatican II, missionary activities in Africa and Asia increased the number of baptized Catholics on those continents. Latin Americans remain the largest continental body of Catholics in the world, with 420 million followers. The number of baptized Catholics in Europe has decreased. Pope John Paul II and now Pope Benedict XVI identified cultural relativism as a primary culprit in this European decline.

Eastern Orthodoxy since 1945

The Eastern Orthodox Churches have always been autocephalous (self-governing), with each headed by a patriarch yet in communion with each other and sharing the same faith. Orthodoxy has historically been centered mostly in the Balkans, Russia, the Caucasus, and other areas under Byzantine and Slavic influence. They have always recognized the four ancient patriarchs of Constantinople, Antioch, Alexandria, and Jeru-

salem with the Patriarch of Constantinople as primary. They often describe themselves as the Church of the Seven Councils, which were held between 325 and 787: Nicaea (325), Constantinople (381), Ephesus (431), Chalcedon (451), Constantinople (553, 680–681), and Nicaea (787).

Following the Great Schism of 1054, the Eastern Churches were treated as heretics by the Western Catholic Christendom. However, while the Orthodox Churches recognize the pope as the chief bishop of Christendom, they reject papal claims of authority. In 1999 Pope John Paul II effectively ended the schism.

Under the rule of the Ottoman Empire, Eastern Orthodoxy suffered but survived in many places. During the Cold War, it was repressed by communist authorities in favor of state atheism. Following the end of the Cold War, a great revival of membership occurred in the former Eastern Bloc countries. One reason was that the churches were opponents of and persecuted targets of communism.

Until 1945, the main Orthodox Churches were in several Middle Eastern countries and in Greece, Serbia, Bulgaria, Russia, Ukraine, Georgia, and Cyprus. However, massive immigration of Greeks and Slavs since the end of World War II has resulted in the expansion of Orthodoxy in the West, especially in Australia, Canada, and the United States. Currently there may be as many as 4 million Eastern Orthodox members in the United States and Canada. The main bodies are the Greek Orthodox Archdiocese and the Orthodox Church of America (previously the American Russian Orthodox Church).

Their main sources for membership have been immigration, intermarriage with non-Orthodox members, children born to members, and conversions from domestic missionary work. The Orthodox Churches, as with other ethnic churches, struggle to maintain an ethnic identity as congregation members acculturate to new regions. Among the common changes is the switch to English from Russian, Greek, Serbian, Syrian, or other original language. As the local national language is substituted for the original language, the original ethnic identity of the members of the Orthodox Church usually declines, but adherence to the original ecclesiastical tradition that is

adapted to the country where they are now living increases.

In Australia, immigrant Orthodox Churches were established following the large immigration of East Europeans after World War II. In South America and in Africa, significant communities have also developed in the postwar era. The spread of Eastern Orthodoxy has changed it from a collection of churches in a diaspora into a growing global presence.

Eastern Orthodoxy is currently engaged in ecumenical relations with the other churches of the world. Engagement has included participating in the World Council of Churches and in dialogues with Roman Catholicism and with various Protestant denominations.

Protestantism, 1945–Present

Protestantism is one of the three major divisions of Christianity, with roots in the sixteenth-century European religious schisms of the Reformation. Protestantism is unique because hundreds of different Christian religious sects and denominations classify themselves as Protestant rather than Orthodox or Catholic. Protestantism is difficult to define on a global scale but easier to describe. Although Protestant sects are historically, theologically, socially, and ethnically diverse, they do share a rejection of papal authority, emphasize biblical Scripture, and focus on individual faith. The tenets of Protestantism encompass a variety of religious denominations, remain open to flexibility and change, and adapt to infinite cultural and regional contexts. Despite the fact that there are several hundred Protestant denominations, most Protestants are members of the Lutheran, Calvinist (Presbyterian or Reformed), Anabaptist (Amish and Menonites),

A Protestant church in Shanghai, China. Christianity is growing rapidly in China and other Asian countries. (Flickr)

Anglican (Episcopalians), Methodist, Baptist, and Pentecostal churches. Protestants may also classify themselves as evangelicals, fundamentalists, charismatics, and independents, among many others.

In the first half of the twentieth century Congregationalists, Episcopalians, and Presbyterians constituted the established Protestant denominations in the United States. These mainline Protestant groups, whose members were middle or upper class, educated, of northwestern European ancestry, attracted to liberal and neo-orthodox theologies, and participants in ecumenical activities. These groups included some Baptists, Methodists, Lutherans, and Disciples of Christ whose theologies and practices varied depending on region. Mainline Protestants were com-

➤ PENTECOSTALISM

Pentecostalism is a Protestant expression of Christianity that is found in nearly every country worldwide and claims more than 500 million adherents. Pentecostals trace their movement back to the Pentecost, when the followers of Jesus gathered after his death and experienced gifts of the Holy Spirit. Historically, Pentecostalism is associated with the religious reformation and revival movements of the nineteenth century in Murphy, North Carolina, and Cleveland, Tennessee, and the 1906 revival in Los Angeles. In the 1960s it entered both mainline Protestant churches and thereafter into the lives of many Roman Catholics as the Charismatic movement or as neo-Pentecostalism.

The institutional development of Pentecostalism has been characterized by the proliferation of independent congregations and organized denominations even as it expanded beyond North America and adapted to the lifestyles of disaffected Protestants throughout the world. Buoyed by the rise of globalization after 1945, Pentecostal and related Charismatic movements, or movements that demonstrate and encourage charismata or spiritual gifts, flourished into a multiplicity of forms and became the fastest-growing set of churches within modern Christianity. If accurate, these

figures indicate that within the next century, Pentecostal and Charismatic movements will become numerically the largest form of global Christianity after the Roman Catholic Church and will include a quarter of all Christians.

The genesis of the North American classical Pentecostal movement is associated with a community of mixed ethnicities including members of the African American Holiness Church led by William Joseph Seymour that met in 1906 in a warehouse on Azusa Street in Los Angeles and experienced a spontaneous, emotional communion with the Holy Spirit accompanied by people falling to the ground and speaking in tongues. The modern Pentecostal movement is often characterized by an emphasis on the working of the gifts of the Spirit, including a postconversion experience of baptism in the Holy Spirit and the practice of speaking in tongues, or glossolalia, as an indication of the presence of the Spirit. According to its adherents, the supernatural and miraculous are a part of everyday reality and manifest through faith healers, glossolalia, and other manifestations of the Spirit. Pentecostalism in practice is frequently apocalyptic, and the coming of the Spirit has frequently been linked to the final days of history.

—Michael Gueno

fortable in secular culture, involved in social issues, and held a less exalted view of the Bible than their more evangelical counterparts.

Most Protestants in the West joined the World War II efforts as theologians wrestled with human suffering and just war theory. In the 1940s and 1950s Protestant churches were distracted with war, the spread of fascism, and the rise of communism, but it was a time of religious renewal, revivalism, and growth. During the post-war era Protestants worked together for keeping peace through a host of voluntary denominational associations by donating money to prisoners of war, helping relief efforts, and aiding bombed cities and churches. In 1948 the World Council of Churches (WCC) organized in Amsterdam shortly after the creation of the United Nations to coordinate worldwide humanitarian efforts. An ecumenical movement with the goal of Christian unity, the WCC represented mostly mainline Protestant traditions but also the Eastern Orthodox and independent traditions.

The Eisenhower era in the United States (1953–1961) was one of religious renewal and revival during which mainstream Protestantism flourished. Record numbers of Americans reported that they believed in God, a statistic higher than any other industrialized nation. According to the 1957 U.S. Census Bureau, out of a population of 120 million, 70 million Americans thought of themselves as Protestant. In postwar America families were flocking to the suburbs, and steeples were erected across the increasingly sprawling landscapes. There was a literal presence of religion in the nation as Protestant churches participated in a building boom, experimenting with traditional and contemporary forms of architecture. Some revivalists took their message beyond the walls of the church. Reverend Billy Graham emerged as an evangelist whose message of individual conversion and social responsibility appealed to thousands during his big city and worldwide crusades at parks, fields, and stadiums.

In the 1960s mainline Protestantism in the United States declined amid debates over race, the Vietnam War, feminism, and sexuality. From the 1960s onward, while mainline Protestant membership declined, evangelicals, who empha-

sized born again or conversion experiences, the centrality of the Bible, and otherworldly spirituality, grew to have a major cultural influence on Protestantism in the late twentieth and early twenty-first centuries.

Most Protestant growth, specifically evangelical and Pentecostal success, over the last 50 years has happened not in the West but rather in Asia, Africa, and Latin America. North American and European Protestant membership and attendance have declined in comparison to the global scope of Protestant growth. Since World War II, Protestant growth has been higher in Asia than any other continent. In the 1980s the number of evangelicals in Asia doubled as Protestants flourished in China, South Korea, and Indonesia. Presbyterians fill megachurches in Korea, while China has the largest number of Pentecostals.

Although Western Protestant missionaries arrived in Africa in the 1700s, Protestantism spread through Africa via African preachers, thus integrating African folk culture and symbolism into Christian rituals. Thousands of independent Protestant churches devoid of Western oversight make Africa the continent with the highest number of Christians. Most African Protestants emphasize Pentecostal or charismatic forms of worship involving healing, exorcism, music, and dance. The same is true in Latin America, the birthplace of Catholic liberation theology in the 1960s. This social movement also attracted liberal Protestants, yet it is the more theologically and politically conservative Pentecostals, however, who now dominate the Latin American Protestant landscape.

Judaism since 1945

Developments in Judaism since 1945 include the aftermath of the Holocaust, the migration of large numbers of Jews to Israel and the West, and the relationship of Judaism to the politics of the State of Israel. Reformist movements within Judaism in the West, particularly within the Reform, Conservative, and Orthodox branches, continued during this period especially in the United States and Britain.

The destruction of the European Jews under the Third Reich eliminated the center of world Jewry in Eastern Europe, making the United States and Israel the centers for theological debate and reforms within Judaism. The exodus of Ashkenazim (Eastern European Jews) who were survivors of the Holocaust primarily from Poland to places such as Australia, New Zealand, the United States, Canada, and Israel had a significant impact on the developments within Judaism in those countries. Moreover, the establishment of the State of Israel led to divisions between Zionist and anti-Zionist strands within Judaism and arguments against the political and theological validity of the Jewish state. These divisions were further complicated by Israel's regional conflicts with the Arab states and global anti-Semitism.

The Holocaust and subsequent migrations truly made Judaism a world religion, as Eastern Europe with its annihilated Jewish population was no longer the centuries-old center of world Jewry. However, well before 1945, the primarily Ashkenazi Jewish Diaspora in the United States and Britain had already made significant reforms within their respective branches of Reform, Conservative, and Orthodox practices, many of which pertained to allowing the observance of Jewish law while existing in a non-Jewish secular milieu, albeit at differing levels. Reform Judaism, which had originated in Germany in the nineteenth century and had a far more progressive and liberal agenda, allowed more leeway in the observation of the 613 commandments (for example, a complete rejection of kosher food laws and of certain gender restrictions), with the Orthodox preferring far more traditional interpretations of and adherence to Jewish law. Conservatism had emerged as a compromise solution

at the turn of the twentieth century as the new Orthodox immigrants from Russia attempted to coexist with the population of primarily reform Jews settled during earlier waves of immigration.

The various social movements of the 1960s in the West, such as second-wave feminism, advocacy for civil rights, and the antiwar movement, influenced Judaism significantly, as many Jews found these to resonate with their own historical struggles as a people. This allowed theological interpretations within all branches to enter the public sphere as advocates of social change. Feminism changed Jewish practice. Reform and Conservative synagogues allowed women to enter rabbinic studies and become rabbis and also allowed bat mitzvah ceremonies for Jewish girls who had studied Torah. As of the early twenty-first century, Orthodox synagogues continued to debate whether women should be allowed to read directly from the Torah, but many do offer a somewhat reduced bat mitzvah ceremony, and some Orthodox women rabbis have been ordained in rabbinical schools.

Jewish migration to Israel accelerated after the establishment of the State of Israel in 1948. Immigrants came not just from Eastern Europe but also from the Middle East, North Africa, and even North America (and later from the Soviet Union and Africa). Israel's shifting demographics had a significant impact on the relationship between Judaism and the diffuse Jewish diaspora. The initial drive to form the State of Israel, mostly by socialists, developed for many religiously minded Jews into a theological project, with the settlement regarded for some as the fulfillment of religious prophecy. The subsequent Arab-Israeli conflicts further divided Diaspora Jews into those advocating that state's expansionist policies, those who sought moderation and peaceful coexistence with Arab states and Palestinian refugees, and a fringe that negated the existence of the state. Zionists, many of whom were Orthodox Jews, advocated the expansion of the state as a necessity for ensuring it as the homeland to all the world's Jews to which they would all return and thus herald the Messiah. Many Reform and Conservative Jews, while supporting the existence of the State of Israel, had more conflicting views on this issue. The theological underpinnings of the State of Israel as the

homeland of the world's Jews and the adherence of many Diasporic Jews to identify with their host nation is certainly one of the major divisions within the world's Jewish community. Both radical Zionists and anti-Zionist Jews remain on the fringes of this theological debate, illustrating its complexity in Judaism.

Judaism has many diverse groups. Sephardic Jews (originally from Spain and Portugal), from various regions in the Mediterranean, follow a form of Judaism heavily influenced by Islam and Middle Eastern culture, albeit with a more lax interpretation of Jewish law than the more orthodox Ashkenazi. However, within recent decades the Sephardim, many of whom have immigrated to Israel and the West, have come under the influence of the trends of Ashkenazim. Within the Ashkenazi, the Hasidim, an ecstatic sect of orthodoxy that developed in the eighteenth century in Poland, currently exist in many Jewish communities in the West and are easily identified by their clothing and more austere quotidian lifeways. The most widespread of the Hasidic groups, the Lubavitcher Hasidim, also known as Chabad, have made significant inroads in the West and Israel. The Lubavitcher Movement is

active in returning Jews to the faith or imbuing more traditional practices on more liberal Jews. Other strands of Judaism, particularly Kabbalah, which emphasizes the more mystical dimension of Judaism and its relationship to self-realization, have also become a trend in recent decades among some Jews and non-Jews.

Since the end of World War II, there has been an emergent trend of cultural or secular Judaism, meaning Jews who identify with Jewish culture and identity but have little to no adherence to the faith. Inter marriage with non-Jews and the possible fading of Jewish identity have raised concerns in Jewish communities. With the depletion of a third of the world's Jews in the Holocaust (6 million), the global Jewish population has only approximately its pre-Holocaust total (an estimated 18 million) at the turn of the twenty-first century.

■ Introduction: Modern Religious Trends

The dropping of atom bombs on Hiroshima and Nagasaki marked the end of World War II and also ended the liberal Christian vision of a world of progress. The flames of firebombed cities and the vanishing of tens of thousands of people in a blinding flash opened the door to apocalyptic visions of a coming doomsday. Apocalyptic theologies expanded their appeal following World War II.

While millennialist thought suggesting the birth of a new world, common to Christianity and New Age theology, for example, need not imply a violent end of the current world, some of the more radical apocalyptic groups have encouraged violence. In the case of Jim Jones and the People's Temple, virtually the whole cult committed mass suicide in Guyana in 1978 after murdering a U.S. congressman and others who

had come to investigate the cult. Technology and science fiction-based notions played a role in the mass suicide of the Heaven's Gate cult led by Martin Applewhite at San Diego in 1997. This UFO religion asserted that the earth was going to experience an apocalyptic end that would wipe it clean, and the only way to escape was to leave immediately. Other apocalyptic groups, seeking to fulfill prophecy, have moved to Israel or have prepared to do so. Some, as the year 2000 approached, expected terrible things to happen at this purported marker of a millennium. These gathered in a year's supply of food, armed themselves in fortified locations, and awaited the apocalypse that never arrived.

Secular humanism has continued to appeal to those who see in science and rationality the means for progress and a basis for ethics. It is

based on the assumption that humans are capable of rationality, emphasizing the use of critical reason and factual evidence for making decisions. Secular humanism's pedigree stretches back centuries, as does Christian humanism. For humanists of all kinds, people are important. Why they are important is the crucial point that distinguishes them. Christian humanism taught that people are important because the historical Jesus died to save all people. They are therefore to be valued as worth the price of the suffering death of the Christian messiah.

In recent decades, the materialism of consumer culture alienated great numbers of people who have wished to turn away from industrial society and return to nature for a somewhat inchoate spirituality separate from organized denominations. A variety of spiritualities have emerged especially since the 1970s that have accompanied the growth of the environmental movement. Millions of people have left churches and synagogues in the West in order to practice some form of religion that is more of an individualistic nature worship. Some have turned to atheism, but it has never gained great popularity even though it has a number of intellectually astute champions, as evidenced in works such as Richard Dawkins, *The God Delusion* (2006). Historically the United States has had a secularist public policy that, arguably, has driven people into ever more intense forms of private devotions. The effect has been to make the United States the most fertile grounds in the world in the last 300 years for the development of new religions. From the First Great Awakening (begun in 1725) through the rise of Pentecostalism in the early 1900s to the Reverend Billy Graham's crusades of the postwar period, public secularism has intensified religious belief and expression in the United States.

These American expressions of faith have spread globally through the missionary work of Roman Catholicism, Protestantism, and the numerous sects and cults that emerged in U.S. religious history. Zealous for the spread of their faiths, these groups engaged in a growing program of mission work that took large numbers of believers to Third World countries on mission trips (or to permanent mission stations) to engage

in hands-on humanitarian missions that supported the preaching and teaching of local indigenous pastors. The effect was great growth in fundamentalist churches, especially of the Pentecostal forms. By 1973 the demographic balance among Christians had shifted from Europe and North America to the Third World. The growth of Christianity in the Third World was also largely in the conservative and fundamentalist churches.

In return, open immigration to the United States and Europe brought millions of Third World conservative and fundamentalist Christian (as well as Islamic) immigrants to these countries. As liberal churches adopted increasingly liberal social pronouncements, millions of church members left to become members of conservative or fundamentalist churches. Other Protestant churches and television ministries adopted a more consumer-friendly attitude and developed into megachurches that stress the therapeutic value of religion and of a social community. With the struggle in the mainline Protestant churches regarding the spiritual status of open homosexuals, many individual churches also withdrew from more accepting organizations, becoming members of conservative or fundamentalist Third World denominations.

"Fundamentalism" is a term that arose within American Protestantism. It was originally applied to those who listed a few fundamental beliefs as defining true Christians. The term, however, has been applied in a more blanket fashion in recent decades to religiously based groups that reject aspects of modernity. Most fundamentalist expressions of faith accept modern technology but reject any worldview, scientific or otherwise, that marginalizes the importance of religious faith. Fundamentalist groups set themselves apart yet seek to influence mainstream society through persuasion and politics, often based on a vision of redemption; in this pursuit, fundamentalist fringe groups at times may resort to and even celebrate violence as a method. Assassinations (for example, of political leaders or abortion doctors), suicide bombings, and hijackings all often have a justification in a religion-based ideology.

—Jack Waskey

Globalization of World Religions

While all major world religions have experienced periods of expansion, decline, and change in earlier eras, during the twentieth and early twenty-first centuries Islam, Hinduism, Buddhism, and other faiths all became less rooted in specific locations or regions and spread out of their Asian homelands in significant numbers to new places in Europe, Africa, and the Americas. This globalization is part of a transnational phenomenon and includes religious and cultural factors as well as the more familiar economic, social, and political processes, all contributing to the emergence of a single world system that transcends economics and other historical limitations. Stimulated by the impact of colonialism, war, world trade, and other factors, global flows of recent migrants from Asia have not resulted in severed ties with their countries of origin. Rather, these migrants maintain significant and lasting contacts with their countries of origin. Global religions provide an important and continuing influence in their diasporic communities, offering religious institutions, cultural networks, and other linkages. Away from home in a strange land, migrants gain a strong sense of identity from continuing participation in their religion, including language, foodways, status, common activities, and access to a wider world. Unlike in the homelands, migrants' places of worship, mosques and temples alike, often become centers of diasporic community life.

As the world's second-largest religion, Islam long since moved beyond its place of origin among the Arabic-speaking peoples of West Asia and North Africa, which today make up only 20 percent of its 1.2 billion adherents. While the bulk of the world's Muslims now live in Indonesia, Pakistan, Bangladesh, India, and Nigeria, Islam has become not only the fastest-growing but also the second- or third-largest religion in many West European and North American nations in recent decades. For example, France's Muslim population, which originated mostly in its former North African colonial region, approaches 10 percent of the total and exceeds both Protestants and Jews.

While estimates vary widely from three million to five million in the United States, two-

thirds of Muslim immigrants and their descendants stem from West and South Asia and frequently are businesspersons, professionals, academics, and students. The remainder are either African American or white converts and include quasi-Islamic groups such as the Nation of Islam, which combines aspects of Islam with black nationalism.

Despite increases based on immigration, conversion, and birthrate, the large Muslim communities in Europe and America have recently had to face the challenges of negative stereotypes and local resentments stemming from conflicts associated with the September 11, 2001, terrorist attacks and the threats of global terrorism. Muslims, whose communities often center on the local mosques, continue to face the pressures of assimilation and integration from the secular or Christian majorities in the West, but some segments of their communities have firmly resisted the loss of their identity as a distinct religious minority, as often symbolized by the wearing of religious apparel such as the hijab, or headscarf.

The world's third-largest religion behind Christianity and Islam, Hinduism numbers just under one billion adherents worldwide. With the South Asian subcontinent, and particularly the nations of India and Nepal, as the heartland of this second fastest-growing world religion, Hinduism thrives despite the fact that it is more of a huge family of religious practices and beliefs than a unified or centralized religion, or perhaps it thrives for this reason. Some of the greatest differences within Hinduism are reflected in variation between geographic and cultural regions, especially between North and South India. These differences are often reflected in the globalized expressions of Hindu migrant communities and their temples around the world.

In addition to increasing awareness of isolated ideas and practices of Hindu spirituality and philosophy such as yoga and meditation, North America and Europe are home to increasingly large Hindu diaspora settlements including both first- and second-generation members. During the time of the British Empire, Hinduism established growing communities in Britain, Canada, other parts of the empire, and the United States. In America, the Indian community, whose

members are mostly Hindu, represents the minority group with the highest per capita income level.

Similar to Hinduism, the South Asian subcontinent is home to two other religions of growing importance, Sikhism and Jainism, that developed as separate religions from Hinduism despite their common roots. Over 90 percent of the world's 24 million Sikhs live in India, mostly concentrated in the northern state of Punjab. Sikh communities, which focus on the local gurdwara, or place of worship, have spread to Britain, the Americas, and former territories of the British Empire. The largest Sikh community outside of South Asia is in the United States and numbers over 500,000 adherents. Also originating in India, the ancient religion of almost 5 million Jains has spread along with the worldwide Hindu migration, mainly through the English-speaking world. Abroad, Jains sometimes share religious facilities with the much larger Hindu community and may inaccurately be lumped in with the larger Hindu population, despite their distinct religious beliefs. Jains in the United States number about 75,000.

One of the most adaptable of the world's religions, Buddhism originated below the Himalayas in South Asia but spread early on throughout Central, East, and Southeast Asia. The earliest missionary religion, Buddhism today numbers over 350 million followers, with over 95 percent still in Asia. In global size, Buddhists are approximately equal in numbers to Protestant Christians in North America. Within Buddhism, different practices identify the larger Theravada, or Northern Buddhist tradition, of East Asia and the smaller Theravada, or Southern Buddhist grouping, concentrated in Southeast Asia.

In the years of Western colonialism, Buddhism benefited by a reverse flow westward during the early decades of the twentieth century, carried by both migrants and European and American converts. Early Western fascination with the Japanese Zen school of Mahayana Buddhism focused on its perceived adaptability to a secular and scientific worldview. In Europe and North America the historic Buddha popularly appeared to many as a sympathetic, nontheistic, reform-minded teacher. Interest in Buddhist meditation reinforced similar Hindu practices among

Western intellectuals, especially among the avant-garde in the arts and psychology. Interest in Japanese Zen Buddhism emerged in the post-World War II United States as Japanese culture was rediscovered during the occupation years.

Buddhist migrants accompanied the global expansion of Asian economies of the late twentieth century. By 2006, the numbers of Buddhists exceeded 3 million in the United States and 1.5 million in Europe and numbered about 700,000 in Latin America, especially Ecuador and Brazil. The largest percentage of Buddhists in America are Southeast Asian migrants.

Secularism

Secularism can refer to one of two ideological positions. First, in politics and government, secularism argues for a separation between church and state. Second, as an all-encompassing worldview, secularism argues for a rejection of traditionally religious ideologies, especially as they relate to human ethics, activities, and decisions. Secularism is not the equivalent of atheism, nor does it mandate that an individual must not be religious. Many secularists, especially those espousing the separation between church and state, believe in some form of higher power and affiliate with a religious body.

Both of these ideological positions have historical precedent. One well-known historical predecessor of secularism in the United States is Thomas Jefferson (1743–1826), who argued for a “wall of separation” between church and state. Most historians also agree that Jefferson

was a deist, an early form of secularism that separated belief in deity from organized religion. While still maintaining a belief in a deity, Jefferson did not believe that morality required divine sanction but rather believed that it should rest on reason and nature alone.

While the ideological positions outlined above argue for specific beliefs, policies, and practices, scholars continue to debate whether actual beliefs, policies, and practices have fallen in line with the secularist position. As regards the first ideological position, a separation between religion and government, some scholars argue that even in secular societies religions can and do still influence governments and public policy. Others argue that the media exaggerates the influence of religions in public life. Both muster evidence to support their claims. Roman Catholicism, for example, was influential in the Polish overthrow of communism in the late 1980s and early 1990s. Religion, in other cases, may offer only an elusive power. For example, the U.S. media depicted the Moral Majority, a politico-religious movement during the 1980s, as holding substantial political clout. However, the movement lost much of its support within a decade of its founding and dissolved in 1989 with many of its goals not realized.

As for whether the second understanding of secularism—that is, as a worldview—is spreading, scholars see this as a complex question that is relative to both historical measures of secularism and sociopolitical factors of individual nation-states. The populations of countries in Western Europe as well as in Australia, New Zealand, Canada, and Japan are widely recognized as having high levels of adherence to secular ideology. In contrast, secularism is almost nonexistent in some nations, such as modern-day Iran, an Islamic republic. Secularism has mixed support in the United States. Current research finds that 50 percent of Americans support a wall of separation between church and state, while 32 percent believe that the federal government should “protect America’s religious heritage” by favoring Protestant Christianity (18 percent are undecided). Support for government involvement with religion varies by issue, ranging from almost 90 percent of Americans supporting the federal government providing military chaplains to around

➤ MADALYN MURRAY O’HAIR

Madalyn Murray O’Hair (1919–1995) was an outspoken advocate of secularism in the United States during the second half of the twentieth century. Ms. O’Hair’s public involvement with secularism began in 1960 with her role in the case *Murray v. Curlett*, in which Ms. O’Hair filed suit against a Baltimore, Maryland, school district over Bible readings in public school. Ms. O’Hair claimed that it was unconstitutional for her son, William Murray, to participate in these readings as an atheist. The *Murray v. Curlett* case was consolidated with *Abington Township School District v. Schempp*, a similar case against a Pennsylvania school district, when brought before the Supreme Court. The case was decided in favor of the plaintiffs (Murray and Schempp) in 1963. The decision effectively outlawed the forcing of students to participate in sectarian religious rituals (i.e., prayer and reading the Bible) in public schools.

As a result of this very public case, Ms. O’Hair became so infamous as to be declared by *Life* magazine in 1964 “the most hated woman in America.” Part of this ire resulted from her very open declaration of atheism. Ms. O’Hair organized the precursor organizations to one of the more prominent pro secularism organizations in the United States, American Atheists, in 1963. American Atheists works for the civil liberties of atheists and the separation of government and religion. Ms. O’Hair remained at the helm of the American Atheists until 1995 when, in a tragic and bizarre case, an associate kidnapped and murdered her and her two children and made off with funds from one of the groups that Ms. O’Hair founded.

30 percent of Americans supporting teaching religious values in public schools.

Early proponents of secularism and its accompanying process, secularization, argued that the modernization and rationalization of society would inevitably lead to increasingly secular

societies and people without specifically describing any mechanisms. More recent scholarship argues instead that secularism, like other social movements, spreads through the actions of activist groups and individuals. The International Humanist and Ethical Union (IHEU) is an umbrella organization embracing secular movements and groups worldwide. Founded in Amsterdam in 1952, the group now represents the views of over 100 national organizations in over 40 countries, with a combined membership of over 3 million. The goal of the organization is to spread secularism (also called humanism or secular humanism) in the belief that a secular worldview, rather than religious ideology, provides a stronger foundation for human rights, ethics, and morals.

Atheism

Atheism is a difficult category to historically trace because many who subscribe to an atheistic worldview—that is, the disbelief of a deity or deities—do not self-identify as atheists. The reasons for such a rejection vary, but alternative labels are numerous, many of them having a complex history of their own. Some of these include Freethinkers, Secular Humanists, Anti-theists, Skeptics, Rationalists, and Brights, to name but a few. In addition, groups and individuals that were outside of mainstream Protestant Christianity were at times referred to as atheists, even if they

were theistic. Therefore, to trace a history of atheism is a complex undertaking that requires scholars to contend with multiple forms of identity and mislabeling. There are specific historical moments, however, where the terms “atheism” and “atheist” have been specifically used for political, social, and cultural motivations.

Tensions between atheists and religious groups in the post-World War II era have been most prevalent in the United States, as Europe entered an era of rapid secularization at all levels of society while the United States continued to experience an increase of religious fervor. In the United States in 1948, Vashti McCollum brought national attention to atheists when she sued the school board in Champagne, Illinois, over the practice of allowing school time for religious teachings. She argued that her son was being discriminated against as an atheist and was pressured to attend one of the sessions for Christianity, Catholicism, or Judaism. The Supreme Court ruled in favor of McCollum, citing that the school district's practice was a violation of the separation of church and state and the Fourteenth Amendment's Equal Protection Clause.

At the time of the McCollum decision anti-Catholicism was rampant in the nation, a bias that, according to some, helped to sway the Court in favor of McCollum. Although her position as an atheist did not avoid criticism, church organizations such as the Southern Baptist Convention supported McCollum, uniting against Catholic influence in schools. As anticommunist rhetoric continued to spread, however, it was becoming increasingly difficult to openly assert that one was an atheist. With the rise of McCarthyism, communism and atheism were often viewed as synonymous, and thus atheists were eyed with suspicion as unpatriotic threats to the nation-state.

Even though it was harder to self-identify as an atheist in Western countries in the 1950s, organizations continued to distribute publications with atheist messages at the height of McCarthyism. The Freethinkers of America, the United Secularists of America, and the National Liberal League published essays that were critical of religion and presented an alternative worldview to Protestant ideology. Many articles within their publications attempted to clarify that

not all atheists were sympathetic to communists in an attempt to distance themselves from Cold War paranoia. In addition, there were several independent publications promoting atheism that emerged throughout the United States in the postwar period.

The same year as the ruling on *McCollum v. Board of Education*, the United Nations drafted Article 18 of the Universal Declaration of Human Rights. Specifically dealing with freedom of religion, the following decade would involve debates over whether or not atheists were also protected under the word “belief,” as laid out in the declaration. The Soviet Union argued that freedom of religion was different from freedom of thought, a stance that others supported, placing atheism in line with philosophical thought and scientific reasoning instead of religion. It was not until 1960 that the influential Krishnaswami Report stated that atheism should indeed be protected as a belief.

In 1960 another landmark case in the United States was brought forward by an outspoken atheist, Madalyn Murray, who sued a junior high school in Baltimore for requiring students to read the Bible and recite the Lord’s Prayer. In 1963 the Supreme Court ruling sided with Murray, finding the junior high school’s practices in violation of the First Amendment’s Establishment Clause. That same year Murray founded the American Atheists, centering the organization in Austin, Texas. By 1964 *Life* magazine had dubbed her “The most hated woman in America.” Just two years after *Life*’s cover, *Time* magazine questioned “Is God Dead?” in its April 8 issue. Atheism had become highly visible in U.S. popular culture.

With the emergence of new atheist organizations toward the end of the twentieth century such as Atheist Alliance International and the increased visibility of the New Atheists, there are debates about the prevalence of atheists in the world. Local and national atheist groups have emerged all over the world including in Argentina, Cameroon, India, Nigeria, and the Philippines. University campuses across the world have also seen an increase in atheist student organizations. Furthermore, books and the blogosphere have brought more attention to atheism, with scholars such as Richard Dawkins, Daniel Dennett, Christopher Hitchens, and Sam Harris

contributing to a growing literature defending atheistic thought.

The increased visibility of atheists has been met with some hostility, however. In 2006 scholars from the University of Minnesota published a report stating that atheists were the least trusted group in the United States. This attitude is in part fostered by the notion that atheists are amoral and outside of the nation’s so-called religious foundation and are thus incapable of being good citizens. Even with this bias, those who identify as atheists have continued to increase.

Religion, Secularism, and Postcolonial Politics

In the mid-1950s, many former colonies in the developing world achieved political independence from their respective colonial powers. At that time, European and American observers wrote with glee of the spread of nation-states throughout the world. This fervor was for a perceived secular phenomenon. Enthusiasts for the emerging secular nationalism asserted that the legitimacy of government was dependent upon the consent of the governed, irrespective of religious sanctions. Those who promoted the agenda of secular nationalism in the blossoming governments often promoted the separation of

religion and politics as a necessary premise for such nationalism in order to transcend the obstructions to efficacious government and the solidification of political power created by religious orientations. These politicians hoped to define political power in such a way as to deny religious influence over its processes.

The secular nationalism articulated at this time was not entirely divorced from religion. It sought to provide answers to the human need for collective identity, ultimate loyalty, and social structure that has traditionally been the venue of religion in the West. This may be enough to classify secular nationalism as a religion itself. Moreover, critics within the developing world began to recognize a latent Christianity in the peculiarly Western form of secular nationalism. Such Christian overtones may not be overt, but when coupled, for example, with nationalism's quasi-religious structuring role in U.S. society similar to that of orthodox religious traditions within other societies, the continual connection between religion and politics surfaces.

Disregarding such Western calls for secularism, over the next several decades intellectuals in countries recently freed from colonial rule instead expressed the desire for an indigenous religio-political system free from the influence of Western culture. Such calls appeared in Egypt, Ukraine, Sri Lanka, India, Israel, and Mongolia among other countries and peoples throughout the world. In the post-Cold War era, religion has been even more firmly embraced as an alternative to Western imposition and serves as a platform for criticism and hope. The rhetoric of politically active religious leaders throughout the world presents religion as the avenue for change within modern contexts and as a link of continuity with a traditional past. While united against the common enemy of Western secular nationalism, such postcolonial nationalism often utilizes the symbols and ideas of the indigenous culture, including religion, to revitalize the society and religion as a vital element of the public arena. This is a broader social understanding of religion than is traditionally recognized by the Western definition of religion as a matter of private beliefs and precise doctrines. It includes religion in daily life and as founding the cosmological frame-

work that provides legitimation to political states and national loyalty.

Christianity Moves to the Developing World

Late in the nineteenth century, the spread of Catholicism and Protestant Christianity coincided with large-scale industrial development in Western Europe and the United States and with the imperialism of European and American rulers who were eager to develop trade and gain sovereignty over peoples in Africa, Asia, and Latin America. There was indeed a close connection between the Bible and the gun in the Christian penetration into the developing world, which became a mechanism for controlling these native populations. Yet despite the Eurocentric view of Christianity conveyed by Western missionaries, many native converts successfully integrated Christianity with traditional values and customs. This gave rise to new forms of Christian movements in the developing world.

Throughout the twentieth century, Western Christianity's global expansion has marked a dramatic shift in the center of Christianity from Europe and North America to Africa, Asia, and Latin America. The proliferation of mainline Protestant denominations, Pentecostal groups, and indigenous Catholic churches and sects had characterized the religious landscape of the developing world. A wide range of denominational and independent churches began to take shape in the developing world, the most famous examples being the Brazil-based Universal Church of the Kingdom of God (the Igreja Universal do Reino de Deus) and Brazil for Christ (Brasil Para o Cristo), the Redeemed Christian Church of God

in Nigeria, the True Jesus Church and Watchman Nee's Little Flock Movement in China, and the Minjung movement in Korea as well as the liberation theology movement in Latin America.

This phenomenon of church growth was a new global religious development comparable in importance to the growth of Catholicism, Protestantism, and orthodox Christianity in continental Europe, the rise of Islam, and the Buddhist transformation of East Asia. Its success owed much to the efforts of native converts. These native converts took the initiative to integrate Christianity into their communities and networks. Religious specialist Philip Jenkins refers to this religious phenomenon as the rise of "Southern Christianity," as opposed to Western Christianity in the Northern Hemisphere. By nature, the Southern Christianity is an enthusiastic, spontaneous, fundamentalist, and supernatural-oriented religious movement, considerably different from any other branch of Christian denominations in Europe and North America.

Politically, the growth of Southern Christianity coincided with a quest for justice, equality, and community empowerment across the developing world. Many Latin American liberation theologians, African revolutionaries, and Asian freedom fighters drew on their understanding of Christianity for ideas and inspirations in their struggles against colonialism, injustice, poverty, and political oppression.

The politicization of Christianity can best be seen in Africa, where the churches were often the only viable institutions to become involved in political, social, and cultural activities. A good example was the dynamics of Christian activism in South Africa. There was an intense conflict between the Dutch Reformed Protestants who used Christianity to justify apartheid rule and the Africans inspired by Christian principles to oppose it. As symbols of black consciousness, theologians such as Robert Sobukwe, Steve Biko, and Desmond Tutu identified the racist oppressors as those who crucified Jesus Christ, asserting that blacks had God on their side in the struggle for justice and racial equality. They critiqued the otherworldly interpretation of Christianity, as in the white churches, and reinterpreted Christian doctrines in relation to community

empowerment and this-worldly ethics of African religions.

The dynamics of Christianity as a driving force of change served as a form of political mobilization, social renovation, and cultural regeneration. After so many centuries of cross-cultural interaction, Christianity had become an integral part of local politics, religion, and culture in the developing world.

Acceleration of Fundamentalism

The last three decades have witnessed an acceleration of fundamentalism in different religious traditions and countries of the world. While the term "fundamentalism" originated in a conservative Christian context and was first used in a series of pamphlets published between 1910 and 1915, the term has entered popular discourse to refer to movements within various major world religions. Fundamentalists perceive the shift to modernity and secularization as an error, resulting in a loss of ethical and cultural values; each fundamentalist creed has created an alternate ideology in order to redeem society. There has been a conscious effort among these movements to return to authentic religious beliefs and core ethical and moral values of the past, and to this end, many fundamentalist groups participate in modern political and democratic processes.

In Israel, those among the Jewish population who identify themselves as the *haredim* (God-fearing) form the backbone of radical fundamentalism. The haredim attempt to return to the authentic religion of Judaism and revitalize Judaism in response to the reality of a modern secular State of Israel. The haredim, who find

themselves in perpetual conflict with the secular society and state, have built a strong political base. From the 1980s the National Republic Party (NRP) has followed the ideological lead of the fundamentalist group known as Gush Emunim (GE) and its policy of encouraging Jewish settlements. The members of GE and the NRP have succeeded in recent parliamentary elections and continue efforts to base the State of Israel on fundamentalist ideology, exacerbating tensions with Palestinians.

Christian fundamentalism in North America, Latin America, Australia, and New Zealand is shaped by a variety of ideological, organizational, and political forces (including the mainstream denominations). The New Christian Right (NCR) in the United States includes three major groups: the evangelical mainstream represented by Billy Graham and Christianity Today organization, the fundamentalists represented by the deceased Jerry Falwell, and the Pentecostal group led by Pat Robertson. The common thread running among them is the rejection of liberal trends in social practices. These movements draw sharp boundaries between themselves and a wider liberal culture and pointedly condemn homosexuality, pornography, abortion, feminism, and Supreme Court restrictions on prayer in schools. Since 1945, the NCR has created an infrastructure that has helped to reshape the political landscape of the United States.

Fundamentalist movements in Latin America can be characterized in three broad categories: mainline Protestantism, Evangelical Protestantism, and Pentecostal Protestantism. Today most of Latin American Protestant movements are influenced by the fundamentalist movements in the United States and are similar in values, ideas, and ethical conduct. In Latin America, evangelists have mobilized the lower and poor segments of society by establishing local and community development programs, hospitals, schools, and orphanages.

Some of the most important fundamentalist groups in Sunni Islam are the Muslim Brotherhood in Egypt, Jamaat-i-Islami in Pakistan, Darul Islam in Indonesia, the Islamic National Front in Sudan, the Rafah Party in Turkey, and other fundamentalist movements in Algeria, Morocco, and Tunisia. The list must also include various

fundamentalist groups among the Shiites. Their basic contention is to return to the Golden Age of Islam by implementing Sharia as a system of laws based on the teachings of the Quran and Sunna. In the recent past a newer generation of fundamentalist movements in Muslim countries has sprung up that advocate violence.

South Asia's political and social landscape includes Muslim fundamentalists, Hindu fundamentalists, and Sikh fundamentalists. To highlight only one of these, Hindu fundamentalism developed during the period of European colonization and is based on the notion that the Hindu nation is a cultural and religious entity that needs to return to ancient social norms and religious values. As with other such groups, Hindu fundamentalists want these nationalist values reflected in the state apparatus. Hindu fundamentalism as represented by Brahmo Samaj (Society of Brahmo) that emerged in 1839, Arya Samaj (Society of Aryas) that was established in 1875, and Rashtriya Svayamsevak Sangh (National Union Volunteers) that was founded in the 1920s presents varying assertions of Hindu national identity. Brahmo Samaj and Arya Samaj aimed to reform Hindu doctrines and practices in order to legitimize a Hindu religious identity in a secular state. Swami Dayananda Sarasvati, the founder of Arya Samaj, categorically declared in 1877 that India is *aryavarta* (the Golden Land) that should be brought to glory again. In South Asia, fundamentalist groups have been major actors in electoral politics and, at times, have encouraged communal riots and other violence.

Christian Fundamentalism

The term “fundamentalism” derives from a series of pamphlets that appeared between 1910 and 1915 called *The Fundamentals*. These booklets represented an attempt on the part of conservative Protestants to counteract what they saw as a drift toward liberal theology or modernism in mainline Protestant denominations early in the twentieth century. Subtitled *Testimony to the Truth*, these pamphlets contained articles on doctrinal matters written by respected evangelical theologians from North America, Australia, and Great Britain. The idea for such a series came from Lyman Stewart of Union Oil Company of California; he and his brother, Milton, financed their publication and set up a fund to distribute the booklets to Protestant pastors, Sunday school superintendents, and other religious leaders throughout the English-speaking world.

Out of the 90 articles contained in the pamphlets, approximately one-third addressed the contested issue of biblical inspiration, arguing that the Bible is divinely inspired and utterly without error in the original manuscripts. Other articles articulated conservative positions on such issues as the virgin birth of Jesus, the authenticity of miracles, the resurrection, and the Genesis account of creation. Those who subscribed to these doctrines became known as fundamentalists, and the term “fundamentalism” came to refer to the entire movement.

Although the term has since been applied more generally to conservative movements in other religious traditions—Islamic fundamentalism, Hindu fundamentalism, Jewish fundamentalism, and others—the term properly belongs to a movement within North American evangelicalism, which is characterized by a belief in the Bible as God’s revelation to humanity, the centrality of a conversion experience, and the impulse to evangelize or bring others into the fold. Fundamentalism differs from the longer tradition of evangelicalism primarily in the demands on the part of its leaders for separatism, sectarianism, and militancy.

ANTIMODERNISM ON TRIAL

The Scopes trial of 1925 illustrates the tensions that emerged in the 1920s between Christian Fundamentalists and mainstream U.S. society, including Christian modernists who accepted evolutionary teaching. At this trial, attorney Clarence Darrow and politician William Jennings Bryan squared off in the Rhea County courthouse in Dayton, Tennessee, over the teaching of evolution in public schools. Bryan, a fundamentalist and three-time Democratic nominee for president, feared that the teaching of evolution would lead to a kind of social Darwinism and thereby threaten traditional values and democratic principles. Although Bryan won his case—John T. Scopes was convicted of violating the state’s Butler Act (1925), which forbade the teaching of evolution in public classrooms—the press contingent, led by H. L. Mencken, succeeded in painting Bryan and, by extension, all fundamentalists as backwoods country bumpkins who were averse to science and threatened by modernity. The hostility was so intense that many fundamentalists separated from the mainstream, creating new institutions such as separate schools and refusing to vote in popular elections.

—Randall Balmer

Whereas evangelicalism historically has sought to be as winsome as possible in order to attract nonbelievers to the faith, fundamentalists have emphasized the importance of purity in doctrine and lifestyle, even to the point of separating from those who, in the judgment of fundamentalist leaders, fail to adhere to those standards. Fundamentalists, more often than not, wear their sectarianism as a badge, evidence that they have not succumbed to the allure of false doctrine or cultural blandishments.

Fundamentalism has also been described as a militant antimodernism, but that characterization must be qualified. Fundamentalists are not opposed to modernism in the sense of being suspicious of innovation or technology; indeed, fundamentalists (and evangelicals generally) have often been in the vanguard of technology especially communications technology, including radio and television. Fundamentalists have an

► THE PROMISE KEEPERS

The Promise Keepers (PK) began on March 20, 1990, while the University of Colorado football coach Bill McCartney, subsequently generally known as “coach” among PK enthusiasts, and his friend Dave Wardell, the University of Colorado athletic director, were on a three-hour car ride to attend a meeting of the Fellowship for Christian Athletes. The first conference, or PK mass rally, took place in July 1991 in the University of Colorado basketball arena, with 4,200 men in attendance. By 1992 they attracted 52,000 to a conference at Folsom Field, the football stadium at the University of Colorado. By 1996 they drew 1.1 million men to stadiums around the United States and as many as 1 million in 1997 to the mall in Washington, D.C., for a special event, Stand in the Gap. As of 2005, the PK conferences drew typically 35,000–50,000 a year. For 2009, they scheduled only one conference for the year at Folsom Field in Boulder, Colorado. The conferences have included music, drama, humor, multimedia presentations, and sermons. The revivalist nature of the PK likely explains their rapid rise and decline at large-scale events, in that revival inherently inspires an intensity that is difficult to maintain.

As a Christian ministry, the PK follows in a long history of revivalism in the United States. Officially formed as nondenominational and nonpolitical, the PK seeks to energize and unite men of all faiths

and races worldwide under Christianity through what they call the Seven Promises and Seven Statements of Faith. The Promises govern personal behavior and specify aspirational goals to fulfill God’s Word: achieve a loving family, practice truth and integrity, and persevere to uphold the ideals of Christianity in all aspects of life, as described in the Statements of Faith. In the Statements, a Promise Keeper should uphold the inerrancy of Scripture, admit one’s own inherent sinfulness and inadequacy, work to meet the needs of less fortunate people, and promote Christianity as the one true faith to achieve harmony among all people worldwide.

The group also has garnered a great deal of controversy, with critics arguing that the PK can be thought of as having a barely hidden political agenda. Critics note that the group, predominately white, emphasizes gender norms that assume female subordination. In addition, PK leader Bill McCartney’s and other PK speakers’ antiabortion, antigay, and antilesbian rights pronouncements at forums such as Operation Rescue suggest common interests with the New Right and the antifeminist backlash of recent decades. Responding to the PK’s call to responsibility, however, many participants report that the PK has had a vital significance in their lives, and they appreciated the at least overtly nonpolitical orientation.

—George N. Lundskow

aversion to modernity only when it is invested with a moral valence, that is, when modernity appears to authorize a departure from orthodoxy or traditional values, however they might be defined.

Because of the movement’s emphasis on biblical literalism, fundamentalists have devoted much attention to the prophetic passages in the Bible, especially the book of Daniel in the Hebrew Bible and the book of Revelation in the New Testament. Drawing on a nineteenth-century mode of biblical interpretation called dispensationalism, or dispensational premillennialism, fundamentalists, especially in the early decades of the movement, looked for the imminent return of Jesus. According to this dispensationalist scheme, the true believers (those who have

been converted and who remain faithful to the Scriptures) would be raptured, or taken directly into heaven at the second coming of Jesus. Those outside of the faith, including those associated with theological liberalism, would face divine judgment.

Because of this emphasis on the imminent return of Jesus, fundamentalists for much of the twentieth century were adamantly apolitical. If Jesus was coming at any moment, they reasoned, why concern yourself with earthly matters? From the end of the Scopes trial in 1925 until the late 1970s, many fundamentalists refused to participate in the political process; many were not registered to vote. That changed after 1976, however, when the Internal Revenue Service revoked the tax-exempt status of Bob Jones University, a fun-

damentalist school in Greenville, South Carolina, because of its racially discriminatory policies. Various fundamentalist leaders banded together to resist that ruling, thereby sowing the seeds of political activism that germinated into the Religious Right. By the time of the 1980 presidential election, the Religious Right included family values and opposition to homosexuality and abortion in its political agenda. In 1979 the political advocacy group called Moral Majority, for instance, was organized by Jerry Falwell. Falwell, pastor of the Thomas Road Baptist Church in Lynchburg, Virginia, called on his fellow fundamentalists to register and vote in the 1980 election, many of them for the first time.

Finally, fundamentalism can be characterized as confrontational, at least as it has developed in the United States; Falwell, for example, insisted that he was a fundamentalist, not an evangelical. This militancy—on matters of doctrine, ecclesiology (church order), dress, personal behavior, or politics—has prompted George M. Marsden, the preeminent historian of fundamentalism, to remark that the difference between an evangelical and a fundamentalist is that a fundamentalist is “an evangelical who is mad about something.”

Wahabism

Wahabism is an extremist form of Islam that a tiny fraction of the world's Muslims endorse; however, it is the Kingdom of Saudi Arabia's offi-

cial religious doctrine. During the eighteenth century, Wahabism emerged in the Arabian Peninsula, which had officially been part of the Ottoman Empire since the sixteenth century; nevertheless, local tribal chiefs were able to maintain a great deal of autonomy. Some of the underlying convictions of more contemporary Islamist movements can be found in the eighteenth- and nineteenth-century Muslim world, which saw the development of movements such as Wahabism that espoused a return to the earliest period of Islam. In particular, proponents of these movements focused on upholding the original teachings of the Prophet Muhammad and the Quran and on eliminating cultural practices that they deemed un-Islamic; those who advocate such beliefs are sometimes termed “fundamentalist.”

One of the leaders of such a movement was Muhammad ibn Abd al-Wahab (1703–1792), a religious scholar who emphasized an austere interpretation of Islam, the eradication of Sufism (Islamic mysticism), and a purging of popular religious customs, such as visiting saints' shrines. Abd al-Wahab attracted a following of devotees in central Arabia, and in 1745 he formed an alliance with the powerful local chieftain Muhammad ibn Saud. Their affiliation provided religious legitimacy for ibn Saud and military power for al-Wahab as their movement expanded throughout Arabia and captured Mecca in 1803. The Ottomans sent forces to suppress the fledgling state within a few decades, but a century later Abd al-Aziz ibn Saud (1881–1953) established the Kingdom of Saudi Arabia in 1932.

The Saudis' absorption of Wahabism into the state has been systematic ever since its founding. For example, Saudi Arabia has no constitution because the state claims the Quran as its constitution. Unfortunately, the Quran provides almost no protection for citizens in practical terms since it has few passages with explicit commands that could serve as anything comparable to a Bill of Rights. Saudi Arabia's legal system also is not codified and is based on the conservative Hanbali School of Islamic law. Most Muslim countries use some variation of Islamic law that has been blended with Western influences for personal status matters (such as marriage, divorce, custody, and inheritance), while

➤ HUNTINGTON'S THESIS—CLASH OF CIVILIZATIONS

In 1993, U.S. political scientist Samuel Huntington's polemic article "The Clash of Civilizations," published in the widely circulated international relations journal *Foreign Affairs*, touched off a public debate over the post-Cold War world. Huntington argued that post-Cold War international relations would not be determined by "the end of history" (a notion promoted by scholars such as Francis Fukayama) or the preeminence of the West but rather by a "clash of civilizations." According to Huntington, cultural and religious identities, as evidenced by the emergence of Islamist movements, Russian nationalism, and Chinese assertiveness, would replace the ideological antagonisms of the bipolar Cold War. Civilizations, characterized by ethnocultural attributes such as religion, language, and common identity, would create new challenges to Western hegemony, particularly along what Huntington called "cultural fault lines" (e.g., Christian Europe-Muslim Middle East, Hindu India-Muslim Pakistan, and Slavic/Orthodox Russia-Europe). Thus, civilizational identity would pose the greatest source of antagonism in future geopolitical strategies vis-à-vis the West by non-Wests. Moreover, certain civilizations limited to the boundaries of one nation-state (such as Turkey and Japan) would find themselves at odds with adjacent civilizations, regardless of their level of economic development (or Westernization). Western universalist notions of democracy, human rights, and economic liberalism

would be at odds with the cultural traditions of the developing world. The non-Wests would be resistant to what they deemed a form of cultural imperialism, particularly when threatened by instances such as the U.S. war on Iraq of 1990–1991 and accelerated globalization. Moreover, non-Wests such as Iran, Pakistan, and China would be more willing to acquire weapons of mass destruction in order to counter Western (particularly U.S.) firepower in that regard, taking a more assertive stance in what was deemed an era of a supreme U.S. military. Non-state actors, particularly Islamist movements, would be prone to center their anti-American ideology on religious discourses (particularly anti-Zionism) to gain the adherence of their followers and mass support from Muslims in the non-Wests.

Despite an initial adherence to the Huntington thesis by neoconservatives in the West, his argument was immediately scrutinized. Critics pointed out that Huntington overlooked the processes of globalization and its effects of creating commonalities among the vast populations of the world, not to mention the continuity of the myriad ideologies that still transcended the boundaries of nation-states and the remaining primacy of the nation-state itself. Regardless, the Huntington thesis provided a valuable framework, albeit with some oversimplifications and generalizations, from which to examine contemporary world affairs.

—Abraham O. Mendoza

other types of law are based on Western codes. Saudi Arabia is one of the few countries that still uses archaic, severe interpretations of Islamic law for criminal matters as well. Religious scholars also hold powerful positions in the country, and many are related to the royal family. In gender matters, the Wahabi state treats women as second-class citizens in many respects, but women do take advantage of educational and professional opportunities. Likewise, gender segregation has actually facilitated many employment openings for women, especially in medicine and teaching.

The most significant ways in which Wahabism has affected the rise of Islamist movements has been in terms of inspiring certain convictions

and spreading its influence by taking advantage of its base in Saudi. Some groups have supported comparable doctrinal positions such as advocating a return to the origins of Islam and denouncing popular religious practices. Another example is Wahabi's use of the term "jahiliya" (the age of ignorance, which Muslims call the pre-Islamic period) to characterize the current (Muslim) regime, which Sayyid Qutb, the ideologue of the Muslim Brotherhood in Egypt, borrowed in the 1960s. In terms of more general Wahabi influence, the hajj pilgrimage to Mecca and oil revenues have been strategic vehicles. Since the hajj takes place in Saudi Arabia, Wahabis are in an ideal position to exert influence on the millions of Muslims who make the trip every year.

Oil revenues enabled Saudis to form the Muslim World League (a nongovernmental organization) in 1962 with the primary goal of spreading Wahabism, and oil money attracted millions of Muslims to work in the Saudi oil industry during the 1970s, where they were exposed to Wahabi thinking. Saudi oil money has also funded the construction of some 1,500 mosques around the world since the 1950s, and Saudis helped fund the Taliban in order to counter the Soviet invasion of Afghanistan in 1979.

While there are certain parallels between Wahabis and Islamist groups, there are also important distinctions. Most Islamist groups espouse social concerns and, indeed, are able to gain a great deal of community support by providing social services and drawing attention to social causes. Many Islamist groups, moreover, have revolutionary aspirations and actively seek the establishment of an Islamic state. Wahabis, on the other hand, tend to have fewer social concerns and are overwhelmingly conservative. That is, they are hardly advocates of revolution and certainly not in Saudi, although some are willing to criticize the state.

Hindu Fundamentalism

Hindu fundamentalism—or, more properly, Hindu nationalism—is a social and political movement that arose over the course of the twentieth century in tandem with a growing sense of Hindu identity as distinct from other religious identities prominent in India, particularly Islamic identity. Inspired primarily by the writings and thought of Vinayak Damodar Savarkar (1883–1966) and

Madhav Sadashiv Golwalkar (1906–1973), Hindu nationalism is rooted largely in the politics of the Indian independence movement and the traumatic aftermath of the partition of India and Pakistan (1947). It is associated today primarily with the Bharatiya Janata Party (Indian People's Party).

Hindu nationalism, as distinct from other types of religious fundamentalism, is not based on a literalist reading of the Hindu scriptures, nor does it involve claims of Hinduism being the only way to salvation. This is different from, for example, Christian fundamentalism, with its conflict between creationism and evolutionary theory and its agenda of conversion. Indeed, Hindu nationalists sometimes pride themselves on the lack of conflict between Hinduism and modern science as well as on the Hindu teaching that there are many paths to salvation and the tolerance that this teaching is supposed to engender.

Hindu nationalism is better characterized as a political ideology that asserts Hindu supremacy within the Indian nation-state. In much the same way that the Christian Right asserts that the United States is a Christian nation, Hindu nationalists assert that India is a Hindu nation in which non-Hindus are to play a marginal, or even subservient, role. Hindu nationalism shares with other types of religious fundamentalism a general sense of hostility and suspicion toward other religious traditions as well as toward secularism, the latter of which is viewed by Hindu nationalists as a clever ploy to subjugate Hindus to religious minorities in India, such as Muslims and Christians.

The irony of such a doctrine of communal supremacy being upheld by Hindus, who pride themselves, as just mentioned, on the tolerance and pluralism of Hinduism, is not lost on critics of Hindu nationalism, some of whom claim that Hindu nationalism is not truly Hindu and that the phrase “Hindu fundamentalism” is an oxymoron. Hindu nationalists, in turn, typically respond to this criticism by arguing that the intolerance of other religious communities requires a forceful response from the otherwise tolerant Hindu community.

The ideological foundations of Hindu nationalism can be traced to a short treatise written by Savarkar during his imprisonment by the British

in the period of the Indian independence movement. The title of this treatise, *Hindutva*, means “Hindu-ness” and is also the term by which Hindu nationalism is generally known by its supporters. Savarkar defines a Hindu as someone who fulfills three criteria. A Hindu is (1) a citizen of India, (2) of Indian descent, and (3) an adherent of a religious tradition indigenous to the Indian subcontinent (thus including not only Hindus as generally understood but also Jains, Buddhists, and Sikhs). Hinduness, in other words, is coextensive with Indian-ness and does not include Indian Muslims or Christians or practitioners of Hindu spiritual paths who are not Indian or of Indian descent.

Interestingly, however, despite its marginalization of non-Hindu Indians and non-Indian Hindus, some Indian Muslims and Christians have supported Hindu nationalism, even rising to positions of prominence in Hindu nationalist organizations, as have some non-Indian practitioners of Hinduism. Sikander Bakht, for example, an Indian Muslim, became vice president of the Bharatiya Janata Party in 1984, and American Hindu author David Frawley has written numerous works in support of Hindu nationalism. Supporters see Hindu nationalism as a conservative ideology that upholds traditional Indian values.

Hindu nationalism is perceived by its critics to be an ideology that promotes intercommunal tension and violence. Nathuram Godse, who assassinated Mahatma Gandhi, was a Hindu nationalist who blamed Gandhi for the partition of India and felt that Gandhi was too accommodating to the concerns of the Indian Muslim community.

More recently, in 1992, a group of Hindu nationalists demolished a mosque in the town of Ayodhya that they believed had been constructed 500 years earlier on the ruins of a temple marking the birthplace of the Hindu deity Rama, a temple that had itself allegedly been destroyed under the Mughal emperor Babur. This led to widespread communal rioting in which many Hindus and Muslims were killed not only in India but in Pakistan and Bangladesh as well. Later, in 2002, extremely violent riots broke out between Hindus and Muslims in the city of Ahmedabad, in the state of Gujarat, in which the Hindu nationalist government of the state is still suspected to have been complicit.

Though associated primarily with the Bharatiya Janata Party, Hindu nationalism is not a centralized movement but instead is espoused by a variety of political organizations, such as the Rashtriya Swayamsevak Sangh (National Volunteers Organization), the Vishva Hindu Parishad (World Hindu Council), and the Shiv Sena (Army of Shiva). Though these are all, broadly speaking, Hindu nationalist organizations, they do not agree on all issues and often differ in their aims and views on specific topics.

Religious Broadcasting

Preachers have made good use of broadcasting since its inception. In the United States, there were live church services on radio as early as 1921. When the television era began in the late 1940s, many popular preachers in the United States adapted to the new medium. A few were Catholic, such as Bishop Fulton J. Sheen, but the majority came from Protestantism, and of those many were from the Pentecostal tradition. By the early 1980s, with many popular U.S. religious broadcasts and networks, the term “televangelist” came into common use.

Some of the first internationally known televangelists came from the United States and brought their successful crusades (revival meetings) to other countries. For example, Billy Graham, who had already held revival meetings in Berlin and London in the late 1960s, preached in Dortmund, Germany, in April 1970. Using a closed circuit hookup, the revival was broadcast to 15 cities in 11 countries. Another American televangelist was the controversial faith healer

Morris Cerullo, who held miracle crusades in countries such as Nigeria and India during the mid-1970s. By 1982, he had offices in the United States, Canada, England, and Israel. In the early 1990s, Cerullo also was at the forefront of evangelizing in the former Soviet Union. Well-known American TV preacher Pat Robertson's *700 Club* program went on the air in 1966; by the mid-1990s, his Christian Broadcasting Network (CBN) was seen in Asia, Europe, and Latin America. Canadian televangelist David Mainse brought his Christian talk and entertainment program *100 Huntley Street* throughout the United Kingdom in the late 1980s.

It was not only American and Canadian televangelists who brought their electronic church to other countries. In early 2009, a well-known TV preacher from Argentina, Dante Gebel, came to America to preach to Southern California's large Hispanic audience. Gebel was hired by Reverend Robert H. Schuller, pastor of the megachurch known as the Crystal Cathedral and host of the syndicated *Hour of Power*. Another Argentinian-born evangelist, Luis Palau Jr., was so strongly influenced by Billy Graham's preaching that he ultimately came to America and worked as Graham's translator, helping to expand Graham's ministry into Spanish-speaking countries. Palau also set up a bilingual ministry of his own, using both radio and TV to do so.

Preachers all over the world emulated the success of their North American counterparts and used the electronic media to carve out their own niches. Among the most influential has been Mariano "Brother Mike" Velarde, a lay preacher and leader of a Catholic Charismatic movement in the Philippines called El Shaddai. The personable Brother Mike is beloved by his millions of fans. Brother Mike's influence also extends to politics; because of his popularity and his ability to get his followers to do as he asks, he has affected political elections and aroused controversy by endorsing political candidates. He was the spiritual advisor during the regime of scandal-plagued former president Joseph Estrada.

In Nigeria, televangelists have been on the air since the mid-1970s, and nearly all of the TV preachers are Pentecostal. As in America, the Pentecostal style of worship lends itself well to television. It is energetic, enthusiastic, and emo-

➤ MUSLIM TELEVANGELISTS

Although televangelism is usually associated with Christianity, in countries such as Egypt, Saudi Arabia, and Dubai the most popular televangelists are Muslims. As of 2008 there were more than 400 satellite channels in the Arab world, and about 80 of them were devoted entirely to religious broadcasting. These channels feature every type of program, from famous imams teaching lessons from the Holy Quran to young clerics hosting talk shows and giving advice to callers. Some channels are conservative, with imams who deliver fiery sermons from a traditionalist perspective. Other channels identify as moderate, with telegenic young preachers who apply Islam to contemporary problems. Muslim televangelists often use a multimedia approach to reach a wider audience, combining their television shows with postings on their Web sites, selling their DVDs, and even making YouTube videos. Especially popular with young viewers are moderates such as Amr Khaled and Moez Masoud, who broadcast from an Egyptian station, and a young Saudi cleric named Ahmad al-Shugairi. Khaled in particular has an international reputation. A 2007 article in *Time* magazine named him one of the most influential people, comparing his popularity among young Muslims to that of a rock star. But Muslim televangelism is not without controversy. As in the West, critics accuse some preachers of being materialistic and acting like celebrities. Also, within Islam, moderate television preachers accuse traditionalists of presenting a harsh and intolerant version of Islam, while the traditionalists accuse moderates of teaching something that is not Islam at all. Meanwhile, the popularity of Muslim televangelism continues to grow, and more religious channels are going on the air.

—Donna Halper

tional. Nigerian TV services often include faith healing, the driving out of demons, and speaking in tongues. Among the best-known televangelists is Pastor Chris Oyakhilome; his following has extended throughout Africa, and millions have attended his revivals. But he has also been accused of fraud regarding his faith-healing claims. Despite the skeptics, Pastor Chris and other faith-healing televangelists remain popular.

Since India is predominately Hindu, there has been some resistance to Christian evangelists leading revivals. And yet by 2007, India had four Christian satellite networks, and several native-born evangelists had achieved considerable popularity. Perhaps the best-known was Dr. D. G. S. Dhinakaran. A convert to Christianity, he began a radio ministry in the early 1970s known as *Jesus Calls* and subsequently moved over to television, gaining many fans in India, Sri Lanka, and Malaysia. He became friends with Pat Robertson and affiliated with Robertson's Christian Broadcasting Network. Dhinakaran continued to preach until his death in 2008. The Hindu faith also has adapted to the idea of televangelism, with a few gurus using the airwaves to preach, but this too has proven controversial. Some religious leaders believe that it is improper for a guru to become a TV star and that it promotes materialism when TV preachers sell their CDs or DVDs. But other Hindu clerics believe that using modern media to get the message out to a wider audience is beneficial.

In Brazil, televangelists have encountered a similar problem to that of India but for a different reason. Brazil was predominantly Catholic until the rise of televangelists, who brought Pentacostal-style Protestant worship to the airwaves. At the forefront of this movement is Edir Macedo, a convert from Catholicism to Protestantism who founded the Universal Church in 1977, gaining members in both Brazil and Portugal. Despite questions about his church's fundraising tactics, Macedo and his television ministry remain very successful. But his harsh criticism of Catholic doctrines has also made him a figure of controversy.

Despite the controversial image of some in their ranks, other televangelists have been known for the good works they perform. As of 2009, religious broadcasting continued to attract millions of viewers worldwide.

Mormonism since 1945

Founded by Joseph Smith and a handful of followers in 1830, the Church of Jesus Christ of Latter-day Saints, often referred to as the Mormon Church, has grown to over 13 million members worldwide. While it is commonly thought of as an almost exclusively U.S. denomination and is headquartered in Salt Lake City, Utah, by 2007 a slight but growing majority of Mormons lived outside the United States.

In 1947 Mormonism's membership topped one million worldwide. Steady growth in the United States and explosive growth in other countries, especially in Latin America, brought total membership to over four million by 1980, and this number more than tripled to 13 million by 2007. This represents an increase of 1,300 percent in the six-decade period following 1947. In 2004 Mormonism became the fourth-largest Christian denomination in the United States, and in 2007 it had a U.S. membership of more than 5.6 million. In other countries, however, the growth of Mormonism has been even more pronounced. For instance, in 1946 Mexico had only about 6,000 Mormons; however, by 2007 there were more than 1 million Mormons in the country. This type of growth has also occurred throughout much of Central and South America. By 2007 Latin America was home to approximately 4.7 million Mormons. While North and South America constitute the bulk of Mormonism statistically, Mormon congregations exist in more than 160 countries, with many also experiencing rapid growth. The West African country of Ghana, which had barely over 100 members in 1980, by 2007 had nearly 30,000. Globally, this trend has allowed the Mormon Church to grow by 350,000–400,000 members per year, adding another million adherents approximately every three years.

As this growth in membership suggests, Mormon missionary efforts are extensive and worldwide. All young men are expected and commanded to serve a two-year mission for the Mormon Church after reaching age 19. However, those who choose not to go can remain members. Many thousands of women also serve an 18-month mission after reaching age 21, but such service is not expected for women as it is men. In the early twenty-first century, at any given time there were between 50,000 and 60,000 missionaries spreading the Mormon message to every nation that will permit proselytizing.

Mormonism's unique doctrines and practices often have placed it at odds with mainstream Christian denominations. One aspect of Latter-day Saint theology, unique to the Mormon Church, maintains that essential covenants beyond baptism must be made to God, not in the weekly meetinghouses but in the temples. Unlike the weekly worship services at Mormon meetinghouses that are open to all, only Mormons who are judged by the church to be adequately adhering to the religion's tenets are allowed entry to temples. Reflecting the growth in membership, the number of temples has also increased. In 1996 there were only 50 Mormon temples operating worldwide; in 2007 there were 124 temples, ranging from Suva, Fiji, to Helsinki, Finland, with another 12 under construction. The Mormon Church also has a temple inside of communist China despite that country's injunction against Christian evangelizing, having built a temple in Hong Kong just prior to its transfer from British to Chinese control.

In the temples, Mormons perform eternal marriage ceremonies under the Mormon belief that temple marriages and the subsequent family relations can extend beyond death and into the afterlife. Because baptism is deemed essential for salvation, Mormons also practice baptisms for the dead in temples. In these ceremonies, Mormons stand in place of deceased ancestors, who may never have had the opportunity to hear the Gospel as it was restored through Joseph Smith, and are themselves baptized. Mormons believe that everyone who has lived on the earth will have an opportunity to accept the Gospel of Jesus Christ either in mortal life or in the spirit world after death. Their doctrine teaches that all men

and women will be judged according to the lives they lived, according to the knowledge of truth they possessed while they were alive; thus those who die outside the realm of Christianity can still obtain heaven and eternal life. This practice has, at times, generated controversy, particularly when relatives of Jewish Holocaust victims learned that their deceased relatives were being given such proxy baptisms without the family's knowledge or consent. In the mid-1990s Mormon officials agreed to end this practice if the deceased were not direct relatives of members.

Several other key beliefs separate Mormons from most Christian groups. While Mormon theology teaches that salvation can only come through the sacrifice (or atonement) of Jesus, Mormons do not accept the doctrine of the Trinity common among Protestant denominations and Catholicism; Mormons believe that God the Father and Jesus Christ his Son are two separate and distinct beings but are one in purpose. Mormons believe that as in biblical times, God has again visited the earth and called prophets, such as Joseph Smith. The Mormon Church is led by a prophet and 12 men deemed to be called as apostles. These Mormon Church leaders claim to receive new revelations for the whole Church that are passed on to the individual congregations. Furthermore, Mormons accept the Book of Mormon as scripture in addition to the Bible.

The Church of Jesus Christ of Latter-day Saints officially ended plural marriages in 1890 with church president Wilford Woodruff's *Manifesto*, and now such marriages are grounds for excommunication. Breakaway Mormon sects that have viewed Woodruff's *Manifesto* as a heretical compromise to ensure Utah statehood and highly publicized trials have continued to perpetuate a misconception that present-day Mormons practice polygamy. Contemporary Mormons are also noticeable for their commitment to a distinct health code, which requires them to abstain from coffee, tea, tobacco, and alcohol.

Jehovah's Witnesses

Jehovah's Witnesses are members of a worldwide Christian movement that has rapidly grown, especially in the second half of the twentieth century, to its present status of about 6.7 million members. In 2007, Jehovah's Witnesses were listed as the 25th largest church in terms of membership in the United States, with over one million members. Brazil and Mexico both contained hundreds of thousands of Jehovah's Witnesses as well.

Jehovah's Witnesses can trace their roots back to the early 1870s. Charles Taze Russell led a Bible study group that focused on the imminent millennial return of Christ, or the Second Advent. Eventually, the movement grew out of the Millerites, and in 1879 the group began publishing the magazine *Zion's Watch Tower and Herald of Christ's Presence*. Russell's adherents eventually became incorporated in 1884 as the Watch Tower Bible and Tract Society of Pennsylvania. In 1931 the growing religious body changed its name to Jehovah's Witnesses, falling in line with a key part of the group's doctrinal beliefs.

Dramatic growth of the movement occurred following World War II, with membership rising

from about 150,000 to more than 6.741 million worldwide according to the Church's 2006 annual report. The group's membership is distributed over a worldwide geographical area, however, with very few large concentrations. In fact, at the end of 2006, only one nation outside of a few island countries, Zambia, had even one percent of its population that belonged to the Jehovah's Witnesses, though the sparsely populated French Guiana also approached that percentage.

Despite the fact that there were only slightly over one million members in the United States in 2006, the Jehovah's Witnesses have a visibility in that country that far outweighs its numbers. The extensive and energetic proselytizing effort of individual members of the church carries their message to the doorsteps of millions of Americans each year. All members are expected to engage in some level of weekly door-to-door preaching. In fact, in 2006 the Jehovah's Witnesses in the United States claimed to have engaged in over 194 million hours of preaching, a figure that roughly breaks down to an average of over 35 hours per week per member.

Though their door-to-door missionary efforts set them apart from most Christian denominations, their doctrines also set them apart from mainstream Protestant or Catholic groups. Jehovah's Witnesses do not accept the central doctrine of a Holy Trinity. Instead, they believe that Jehovah, God, is himself the creator of the world and all mankind and that Jehovah in turn created Jesus who, as the perfect man, died for all mankind to bring about salvation. Jehovah's Witnesses reject the ideas of heaven and hell as they are taught in most Christian churches. Believing that the doctrine of the immortality of the soul is not biblical, Jehovah's Witnesses claim that "at death humans cease to exist. The dead know, feel, and experience absolutely nothing." The righteous will be resurrected and will live again forever on the earth, which will be made into a garden of Eden-like paradise. According to their teachings, a few select Jehovah's Witnesses will be resurrected to live with Jehovah, a number totaling 144,000.

Other doctrines held by Jehovah's Witnesses have caused controversy in both the political and cultural realm and have further separated Jehovah's Witnesses from others outside of their

➤ JEHOVAH'S WITNESSES IN COURT

From the early 1940s through the mid-1950s, the Jehovah's Witnesses argued several First Amendment cases in the Supreme Court. Testing the "Free Exercise" clause, they defended their religious beliefs and practices and the subsequent judgments permitted them to preach in public parks, trespass on property during door-to-door evangelism, refuse to salute the flag or recite the Pledge of Allegiance, and to claim exemption from the draft. (Technically, Witnesses were not pacifists, as they would fight "Jehovah's War of Armageddon," but they would not fight human wars.) The Witnesses faced severe discrimination on the basis of what was perceived as a lack of patriotism.

—Howell Williams

faith. Believing that holidays (such as Christmas and Easter) and birthday celebrations are not sanctioned by Jehovah, members of the faith refrain from taking part in these common cultural practices. They reject the cross as a symbol that has taken on the traits of idol worship among Christians, and they also believe that Christ was not crucified but that he died on a pole or stake, further justifying their rejection of the cross as a symbol.

Members are to refrain from drunkenness and smoking and take conservative stances opposed to gay marriage, premarital sex, and abortion. Much more controversially, the doctrine of Jehovah's Witnesses maintains that "true Christians will not accept a blood transfusion," pointing to Paul's New Testament instruction for Christians to keep themselves from blood. In the political realm, while Jehovah's Witnesses pay taxes, they do not partake in the political process of any country, seeing such governments as man-made constructs to which they do not owe loyalty. Consequently, they refuse to salute the flag of any nation. They also refuse to fight in the military, causing great difficulties in countries with compulsory military service and leading to jail time and persecution of faithful members in many nations.

Though the growth of the Jehovah's Witnesses has slowed in recent decades, it continues to grow in many nations even as the older, more established Protestant churches decline in membership and attendance. In 2006, the Jehovah's Witnesses experienced a growth of 1.56 percent in the United States, a growth rate only bested (among Christian churches) by the Catholic Church, the Assemblies of God, and the Church of Jesus Christ of Latter-day Saints (Mormons).

Consumerism and Christianity in the United States

While remaining the dominant religion in an increasingly diverse society, Protestant Christianity in the United States has evolved and adapted to the new social and economic realities of consumer society. As such, religion in a mass society can be regarded as a commodity to sell. If religious practice once was an expression of duty and tradition, in its current form it as often fulfills a therapeutic role and as such reflects the surrounding cure culture and entertainment industry. The development of megachurches and television ministries in the United States extend trends that began in the late nineteenth century when evangelical Protestants explored ways to fuse Christianity, education, and entertainment in such forums as the highbrow Chautauqua Movement as well as the mass revival meetings of Dwight L. Moody, Billy Sunday, and Aimee Semple McPherson that relied on pageantry, music, and show business trappings.

As globalization accelerates, Christianity, like all religions, has faced pressure not only from other religions but also from broader cultural and economic forces. Without the support of nation-states or clear and direct ties to a community, the denominations of Christianity must compete

Crystal Cathedral, a Protestant Christian megachurch in Garden Grove, California. Purported to be the largest glass building in the world, the cathedral seats 3,000 for its televised Sunday services. (iStockPhoto.com)

► CHRISTIAN ROCK INDUSTRY

Early Christian rock and roll, referred to as Jesus Music in the 1970s when it developed, later became known as contemporary Christian music (CCM). With 1980s Jesus rockers such as Larry Norman, Randy Mathews, Chuck Gerard, and the group Love Song, contemporary Christian music was born. Jesus Movement convert Paul Stookey of the group Peter, Paul and Mary reportedly preached at Berkeley's Sproul Hall. Kerry Livgren ended his search in the early 1980s, espousing Christianity openly through his group Kansas, which he later left, forming the Christian rock band AD. Fleetwood Mac's Jeremy Spencer joined the rigid and controversial commune the Children of God.

While artists such as Amy Grant and Michael W. Smith helped define CCM, groups such as Petra and the Rez Band provided CCM with rock credentials. Although CCM began on the American West Coast, its influence is global. There is an influx of CCM and praise and worship groups out of Australia and Europe. The Newsboys, Delirious?, and Rebecca St. James are all non-U.S.-based artists in this genre. During the 1980s the CCM industry also began to form its own version of hip hop culture, with groups such as dc Talk paving the way for others.

Over the years the Christian music movement, originally designed to bring immediate conversion, has gained the freedom to function independently of the Christian music establishment. The most obvious example of CCM's shift away from a strictly utilitarian approach to Christian music is seen by its acceptance into the mainstream secular market, enjoying everything from airplay on top-40 radio to tours with major secular artists. Groups such as Jars of Clay and P.O.D. exemplify this.

The Gospel Music Association (GMA) includes CCM, adult contemporary, black gospel, southern gospel, and others. According to statistics on the GMA's Web site, album sales in 1998 amounted to approximately 43 million units. In 2001, the album sales amounted to approximately 50 million units. Christian music sales have increased to a market of nearly \$700 million annually. Thirty-nine percent of these sales were in the CCM/Christian rock genres as of 2006.

—Shawn David Young

in a global marketplace. Like a commodity, Christianity must evolve in relationship to the market such that the consumer configures the religion rather than the religion shaping the individual. Given that Christianity has a minimal core doctrine, it has proven flexible in the global religious market. However, the consumerist orientation tends to reduce personal commitment; people buy things to make life easier, not harder.

Michael Emerson and Christian Smith's recent sociological study indicates that among Christian youths (aged 14–24) in the United States, God functions mostly as a kind of personal therapeutic device who responds to whatever an individual requests. This God plays only a background role at other times. Alan Wolfe's similar study of adults found likewise that personal interests rather than tradition or doctrine most decisively shaped attitudes toward God. Altogether, one's God becomes an expression of one's lifestyle rather than one's lifestyle conforming to God's expectations.

Concerns thus arise as to whether any decidedly Christian or religious center remains if the individual can freely choose a preferred version from innumerable possibilities. The contemporary megachurch phenomenon, in which the church integrates retail businesses and social gatherings under one all-encompassing roof, blends Christian worship with recreation and entertainment and blurs the distinction between religious devotion and other activities. Christianity becomes a lifestyle based on consumer choices rather than on adherence to specific doctrine and mandates. The religious service itself reduces doctrine and requirements to the most minimal content in order to attract the largest number of people, and megachurches are almost all nondenominational. At the same time that the democratization of religion tends to create diversity, megachurches represent a mass-production process that tends to consolidate conformity.

Yet while megachurches generalize and minimize doctrine, various members form small Bible study groups and other intimate ties through friendship networks, and this networking tends to maintain diversity and sophistication within the larger generalized membership. Given the advantage of size yet offering the possibility of

small group diversity, the megachurch phenomenon will likely continue and possibly supplant established denominations, which will become special interest by comparison.

Congruent with the rise of megachurches, a Christian culture industry has developed that parallels secular culture. Through bookstores, music and clothing stores, travel agencies, other retailers, and private schools, entrepreneurs sell Christian culture. This includes popular material, including Christian rock-and-roll recordings, and popular novels once deemed profane. Critics argue that such exposure in the market reduces Christianity to a veneer, with underlying substance no different than secular culture. Consumers nevertheless buy increasing amounts of mass-marketed Christian culture and education, with crossovers to non-Christian markets. Similarly, non-Christian rock bands and books with compatible content now appear in Christian retail establishments, further blending the religious and the secular. In the realm of popular culture, such blending occurs with increasing frequency and ease. While moralists once decried the secularization of U.S. culture, instead it appears that the United States is still a profoundly religious nation, although its religions have adapted to a more consumerist mode.

Counterculture Christianity

A Christian revival called the Jesus People Movement began among the youth subculture of the late 1960s in the United States. It quickly spread across the country and beyond and has had lasting influences on the Evangelical Christianity in the United States. Early converts simply wanted to live like Jesus, reading the Bible literally to the point of selling all possessions and founding Christian hippie communes (now called intentional communities) while citing the Scriptures as a complete guidebook for life and ultimate truth. To some extent the movement was co-opted by conservative Christianity, but counterculture values and politics still inform some of its remaining groups.

As Jesus Movement converts, or Jesus freaks, came of age, they sought autonomy. Burgeoning new fellowships seemed to fall into the same trap as the very middle American denominationism that they opposed. New converts fled organizational structure only to create their own brand of denominational exclusivity. As a result, Jesus freaks began to disengage from society, adopting a mixture of orthodox Christianity and a concern for social justice, which was slowly erased by a growing cultural conservatism. With a growing interest in apocalyptic eschatology, Jesus Movement communes looked to the early church in the book of Acts, preaching a sort of separatism and leading members to pursue a temporary utopian structure until the second coming of Christ.

The Children of God (later known as The Family) was led by Protestant David Berg (1919–1994). It became an example of the extremes that new converts might follow in their countercultural experiments in living a biblically oriented Christian life. After media hype and continuing pressure, the Children of God relocated to Europe. It is still in operation and appears as any mainstream Protestant church. The controversial side of this group included charges of sexual abuse as well as their avowed method of proselytizing known as flirty fishing. The women made sexual overtures to men for the purpose of evangelizing. This group rejected the system and espoused Apocalypticism. Berg's *Mo Letters*

➤ JEWS FOR JESUS

Jews for Jesus (JFJ) is an organization composed almost entirely of Jews who believe that they have completed their Judaism by accepting Jesus of Nazareth as the Messiah. A major focus of the group is its proselytizing efforts in converting Jewish people to Christianity. The 1960s and early 1970s were something of a heyday for evangelical, nondenominational Christian groups that arose in the United States, and it was in this context in which the group was founded by Moshe (Martin) Rosen. JFJ members identify themselves as Jews despite upholding the teachings of the New Testament. The organization sends missionaries to 11 countries ranging from Israel to Brazil, and it uses unique evangelizing techniques that aim to appeal to Jews.

The JFJ draws criticism from most denominations of Jews and many Christians alike, primarily on account of the organization's controversial beliefs, missionaries' tactics, and Christian Zionist positions. The JFJ's claim that a Jewish person can believe in the Christian New Testament, accept Jesus as her or his Savior, and remain a Jew is a concept that most Jews and Christians oppose. Jewish critics further maintain that such ideas are tantamount to dismissing Judaism as a religion by reducing Judaism to its cultural and ethnic components; they also denounce the JFJ's method of emulating Jewish rituals and traditions to attract potential converts as being deceptive and unscrupulous. Jewish and Christian opponents further point out that the founder and current executive of the JFJ are Baptist ministers who attended evangelical Bible colleges.

The JFJ can be considered a Christian Zionist organization because of its uncritical support for Israel. The JFJ takes this position because of its literalist interpretation of biblical prophecies and the role of the Jewish people in them. Their convictions likely offend nearly all of Israel/Palestine's population. The JFJ advocates Israel's right to all of historic Palestine, with no regard for the rights of Palestinians, and believes that the return of Jews to Palestine will be followed by their near annihilation during the end times.

—Elizabeth Brownson

was the text in which sect members found extrabiblical confirmation of sect doctrine. As an evangelical tool, this sect also created its 1960s underground-flavored “True Komix” in whose cartoon frames Berg appeared as a lion, the group's flirty fishing was depicted, and Nixon was denounced as “Nitler.”

Another product of the 1970s Jesus Movement was the Living Word Fellowship (LWF), which began in a suburb of San Francisco. This group was Pentecostal in ritual and believed that God would destroy urban America by firestorm. The LWF believed that God had chosen them to prepare for the end. The group purchased land in the Sierras, where they built a small town with a church called the Ark. Operating under theocratic rule, the LWF encouraged members to hold working-class jobs for the purpose of storing up resources for the apocalypse. Members followed a strict moral code of conduct, based upon a literal understanding of the Christian Bible.

While the more controversial groups have gone underground or collapsed, Jesus People USA (JPUSA) still thrives. Founded in 1972 and functioning socialistically, the inner-city Chicago-based JPUSA considers itself an intentional community, citing the book of Acts as their inspiration. They adopt a mixture of orthodox Christianity and a concern for social justice as well as an interest in apocalyptic eschatology and the value of community.

The JPUSA brings its utopian sensibility to the global community through its annual Cornerstone Festival, celebrating music, culture, and ideas. The Cornerstone Festival, which began in 1984 in rural Illinois, has been held every summer since. Web casting links the global community to this Christian version of Woodstock. Attendance has reached 25,000 in years past. In spite of its Christian orientation, this festival offers a place where people can experience a week of reveling in an acceptance of “the other.” Those who attend expect to challenge and to be challenged as they question or rebuild their own notions of cosmic order, developing meta-narratives, giving them a sense of identity and connection to something greater than themselves. This provides, if only temporarily, a collective

agreement of what could be: the possible. When first encountering the festival, band member Jeff the Girl from the punk group Five Iron Frenzy declared, “God, I am in Heaven!”

Attempts to socially engineer the Kingdom of God on earth as a Christian utopia have historically ended in what could be considered dystopian communities. The Cornerstone Festival indicates, however, that the message of 1960s counterculture Christianity still has appeal to contemporary youth culture.

■ Introduction: New Religions and Archaic Revivals

Since 1945 there have been many religious changes, among these the rise of many new religious movements. Some of these are completely new, some are revivals that include elements of older religions, and some are simply more visible now than they were in previous decades. The changes in religion have not fulfilled any “God is dead” visions. Rather, there has been a shift to religion as spirituality and a great religious ferment, including revivals, new syncretic religions, and what are generally described as New Religious Movements (NRMs).

New groups that emerge as purists in the mainstream of a religion seek reforms that will purify it of its obsolete traditions or its errors. These religions tend to be best understood as Accommodationist movements. They use the mainstream religion from which they emerge but then add other elements such as prophecies or rituals. The Unification Church (Moonies) founded by Sun Myung Moon (previously a Protestant minister) presented new teachings to his disciples. Sects that hail their leader as a new prophet with a new revelation have been numerous. Some spinoffs of the Jesus Movement eventually hail their leaders as new prophets. The Children of God (now The Family International), led by David Berg, for example, accepted Berg’s revelations and exhortations to abandon all worldly institutions.

Many new religions, particularly those that first developed in colonized regions and have continued to evolve, are hybrids. They are syncretistic unions of several religions. The religions are usually aspects of Roman Catholicism and pre-Christian native religions. Santeria (“the way of the saints”), for example, is a blend of the religion of the Yorubas of Nigeria and Roman Catholicism that is practiced throughout the Caribbean diaspora.

Other religious movements stress the coming of a new age after an apocalyptic event or a millennium, hence the name “New Age.” Others stress magical practices (thaumaturgical). Other new religions stress healing, communal living, legalistic practices, or devotional practices. All, however, show some elements of syncretism.

Many spirit movements have emerged since 1945. These groups, as did earlier adherents to Swedenborgianism and Spiritualism in the eighteenth and nineteenth centuries, stress contacts with spiritual beings such as angels, ghosts, nature spirits, or other spiritual forces. Religion can appeal to reason, to practices, or to emotions. The spirit movements appeal to the emotions. Some of these also provide their adherents a way to make sense of the world that is technologically strange with teachings about UFOs and extraterrestrial life.

Other new religions offer a new way of thinking about society and its practices. Some of the new feminist spirituality groups are in this category, as are the neo-pagan groups. Neo-pagans seek to revive elements of ancient faiths and include references to Norse, Celtic, and Greco-Roman religions as well as Native American and other indigenous groups' shamanistic practices. Frequently their beliefs stress that nature is sacred. Some feminist groups have identified goddesses who should be worshipped, drawing them primarily from pre-Christian pagan goddesses.

Persecution of religions by governments has been a regular feature in the past century. In China, the new Falun Gong movement, based on Buddhist and Daoist ideas, has been persecuted by the Chinese communist government on the grounds that its healing practices are harmful. Often the persecution is due to the government's fear of a movement that it cannot control. Opposition to new religions has emerged not only in China but also in the former Soviet Union and the East European countries where religion was suppressed during the Cold War. Public concerns about cults have also led to conflicts with NRMs in the United States, Europe, and elsewhere. Sometimes the opposition has been political, such as recent laws in France prohibiting the wearing of religious symbols, aimed primarily at the *hijab* worn by Muslim women, in public schools.

Global migrations have carried religions around the world far from their origins. Religions such as the Hare Krishna Consciousness movement is derived from the Hindu bhakti movements, but like Buddhism it has found many adherents far from India or elsewhere in Asia. They have been imported into new countries, as has Christianity throughout its history or as the Pentecostal Movement has been in Latin America and Africa.

The presence of so many religions crossing all manner of political boundaries has made the world resemble the religious plurality of antiquity.

—Jack Waskey

New Religious Movements

One of the most interesting and often controversial facts about the modern religious land-

scape is the development and growth of religious pluralism. The late twentieth century witnessed a profound growth in New Religious Movements (NRMs). Arising within the context of colonial contact with subjugated cultures and cultural dissatisfaction in Western nations and facilitated by the rise of rapid global travel and communication, the late twentieth century provided fertile soil for the growth of alternative religious ideas and sometimes created a framework for bitter ideological struggles.

Though the number of NRMs increased dramatically after 1945, many have roots in earlier periods. For example, religious groups collectively known as UFO-related religions (e.g., the Raelians, the Ashtar Command, and Heaven's Gate) did not emerge until the 1950s and after and are related to late-nineteenth-century esoteric traditions, particularly Madame Blavatsky's Theosophical Movement. These new religions constructed a UFO mythology that included messengers in alien spacecraft warning of nuclear and, more recently, environmental destruction.

Wicca, witchcraft, and other traditions collectively known as neo-pagan religious movements also arose from the changing historical context of the 1940s and 1950s. For example, the 1951 repeal of England's Witchcraft Act of 1735 was a watershed moment for the development of Wicca. This event made possible the publication of Gerald Gardner's highly influential books *Witchcraft Today* (1954) and *Meaning of Witchcraft* (1959). In these works Gardner laid the groundwork for modern Wicca and created a controversial history of witchcraft by pushing its origins back to pre-Christian European pagan traditions. Wicca and other neo-pagan traditions remain popular with individuals seeking ecologically friendly and loosely structured religious traditions.

The 1960s were a pivotal period for the formation of NRMs. In this period disgruntled baby boomers questioned Western Judeo-Christian culture and experimented with alternative intellectual, philosophical, and religious ideas. Thus, religious ideas associated with Western paganism, indigenous religions, and the East—particularly Hinduism and Buddhism—found a ready audience among dissatisfied youths. This is demonstrated by the influence of Transcendental Meditation

and its founder Maharishi Mahesh Yogi (1917–2008) and the International Society for Krishna Consciousness (Hare Krishna) founded by A. C. Bhaktivedanta Swami Srila Prabhupada (1896–1977).

The development of such groups in Western nations was not without controversy, however. Many Americans reacted negatively as loved ones sometimes gave up possessions and wealth and rejected family and friends to join one of thousands of alternative religious groups. From this negative backlash the so-called cult wars of the 1970s and 1980s commenced.

From the perspectives of the countercult and anticult movements, cult leaders used deceptive and coercive mind control techniques, commonly known as brainwashing, to acquire and maintain membership. This led to the rise of cult deprogrammers, sometimes known by the innocuous term “exit counselors,” and the controversial practice of forcibly removing adherents and subjecting them to a variety of mental and physical coercions in order to break the influence of the cult leader. Those who objected to these practices debunked brainwashing theory and maintained that forced kidnapping of individuals from these religious groups is a violation of constitutionally guaranteed rights to religious freedom.

As the turn of the millennium approached, the late 1980s and the 1990s saw renewed debate concerning the role of violence in NRMs. The 1969 Manson Family killings in California and the 1978 People’s Temple suicides in Guyana already loomed large in the public imagination when reports about violence and ritual killings related to purported Satanic cults emerged in the late 1980s. The alleged ritual killings and reports of sexual abuse were rumor panics having little to do with the activities of established Satanic religions such as Anton LaVey’s Church of Satan. Nevertheless, the high-profile nature of the Manson Family killings, the People’s Temple suicides, and the so-called Satanic panic of the 1980s helped shape a popular willingness to believe that alternative religious movements are prone to violence and deviant behavior.

Such perceptions about alternative religious movements became evident during the 1993 51-day FBI siege of the Branch Davidian community

➤ TERMS OF DEBATE—THE PROBLEM WITH “CULT”

Can the word “cult” be saved? For scholars of alternative religious movements, the term “cult” is used carefully and sparingly. This practice arises from the fact that misperceptions related to the term dominate media depictions and popular discourse. In such depictions the word “cult” conjures images of maniacal masters of brainwashing leading isolated religious groups comprised of zombielike members deprived of possessions, money, family, and individuality. In truth, very few alternative religious groups fit within this discourse, which has caused scholars to shy away from the word “cult” as too loaded with preconceptions for academic use. By far the most common alternative designation is “new religious movements,” often abbreviated as NRMs. This term is not without its problems; determining what constitutes “new,” for example, has generated debate. Others favor the term “alternative religious movements” as a solution. “Alternative” solves the problem of defining “new” by shifting the focus from age to evaluating a religious group against the religiosity of the culture in which it resides. However, “alternative” also suffers from ambiguities because defining what is standard or accepted as opposed to what is alternative depends on a variety of differing contexts and preconceptions.

—Paul Brian Thomas

near Waco, Texas. Though the Branch Davidians are a sect of the Seventh-day Adventist Church, media accounts labeled the group’s leader, David Koresh, as a cult leader guilty of sexual abuse. These assertions supported the perception that the Branch Davidians were a threat, which in turn led to a standoff that ended with the destruction of the community and the burning deaths of 80 Davidians.

Other acts of violence by alternative religious movements received prominent attention in the 1990s, including the Aum Shinrikyō serin gas attacks on the Tokyo subway system in 1995 and the 1997 Heaven’s Gate suicides near San Diego, California. Despite media attention, it is important to remember that such examples stand out because they are exceptional. The few groups that have engaged in violence are hardly

representative of the thousands of alternative religious movements that peacefully coexist all across the world.

As religious pluralism shows no signs of abating, it is evident that more nuanced perspectives on alternative religious movements are required. Too often opinions about these groups are informed by false information, apostate testimony, the opinions of countercult and anticult experts, and preconceived notions regarding deviance and abusiveness within such communities. Therefore, one of the challenges faced by academia, law enforcement and government agencies, and society at large is formulating a more balanced and unbiased approach to religious pluralism and alternative religious worldviews.

New Age Religions

New Age religions are any of a number of religions that have grown out of the international New Age movement, a religious and social movement that coalesced in its presently identifiable form in Western cultures in the late 1960s. The goal of New Age religions is to explain the past, explore the present in a meaningful way, and orient the hope of adherents to a future transformation of self, species, or society. The modern form of New Age is a recent development that emerged from older, more established Western religions and strains of intellectual thought and has integrated religious ideas and traditions from the East. The New Age movement is the latest phase in the development of Western society's occult-metaphysical tradition that has developed historically alongside of Christianity for centuries.

The New Age movement rejects religious orthodoxy. However, the members of the movement do share several common beliefs and values. As its name suggests, New Age adherents anticipate a future era or age in which the perceived mental or metaphysical sicknesses of humankind will be transcended often through individual transformations and experiences. A global transformation and a universal religion will ensue, expressing the root mystical experience underlying each world religion. To bring about such a transformation, adherents promote self-awareness and spiritual exploration to evoke individual inner transformations through mystical awareness referred to alternately as self-awareness, higher consciousness, or self-realization. Many New Age religious organizations and individuals couple this inner process with an active sociopolitical agenda. Frequently the environmental ethic of many New Age religions is itself the social ethic of adherents, as society and the earth are understood to be holistically linked.

New Age religions affirm that religious experience is of greater importance than specific beliefs, which tend to be held only as long as they are efficacious. New Age practitioners generally believe that there are several ways to approach truth that are differentiated only by their ability to produce effects. New Age religion may or may not identify the reality of God. Such a God, if present, may be envisioned in terms of immanence or as of one reality with the universe or may be expressed in a form of dualism in which the spiritual reality is perceived as inherently good and matter as inherently bad. New Age religions generally affirm the existence of disembodied beings that may or may not serve as masters and teachers of humankind. Many New Age religions express belief in karma and reincarnation. Regardless, the power for transformation comes from an omnipresent form of energy that permeates all aspects of existence. This energy is recognized as prana, mind, mana, the chi, or the holy spirit and is the underlying essence of reality.

The beginning of what would grow into the modern metaphysical tradition and New Age religion can be traced to Emanuel Swedenborg, an influential eighteenth-century scientist who

is remembered most for reporting that he communicated with angels and explored the spiritual world through dream states. He developed a complex cosmology that formed the basis for most of the Western metaphysical tradition that followed. Building upon Swedenborg, Franz Anton Mesmer, a Viennese physician, used the existence of a hypothesized universal magnetic fluid to articulate a scientifically influenced worldview through which he could recast conceptions of magic, miraculous healings, and spiritual energy. In early-nineteenth-century America the thought of Swedenborg and Mesmer mingled with Transcendentalism, which incorporated elements of Christianity and Unitarianism to articulate a new religious vision, infused with elements of the religions of India and Asia and American Romanticism, that is best described as pantheistic nature mysticism.

In the 1850s Spiritualism, the first popular synthesis of Swedenborg, Mesmer, and Transcendentalism achieved widespread acceptance in America. Adherents claimed the ability to commune with deceased spirits, prove scientifically the existence of life after death, reveal accurate information about individual lives and the spiritual landscape, and even perform acts of healing. Adherents of Theosophy, begun at the end of the nineteenth century, engaged spirits to learn the history and purpose of life. It rejected Spiritualism's frequent fusion with Christianity and expressed its worldview through a synthesis of metaphysical ideas and science. Theosophy further proposed the existence of masters, a ruling spiritual elite, who controlled reality, guided human society through scientific ideas, and showed humanity a path to a higher existence by descending to the physical world as mortals.

In the twentieth century the rise of humanistic, parapsychology, and transpersonal psychology that examined religious states of mind separated the practice of religious techniques and rituals, particularly meditation, magic, and yogic postures, from the ideological framework with which they were traditionally associated. This disassociation facilitated the free acquisition of these techniques by various individuals and movements within the metaphysical community. Later, following the series of reported sightings of unidentified flying objects, or UFOs, that

➤ GAIA HYPOTHESIS CONTROVERSY

The idea that Earth and its inhabitants are a single organism is not confined to the New Age movement. Scientists confronted a similar concept when James Lovelock presented his Gaia Hypothesis in 1969.

James Lovelock (1919–), an atmospheric specialist, was working for NASA during the 1960s when he learned that the sun had once been 25 percent less luminous. Baffled as to how Earth had sustained life, he developed a hypothesis: The Earth is like a living organism, which regulates conditions on its surface in order to maintain and nurture life. Everything on Earth is interdependent. For example, the uniquely high percentage of oxygen in the Earth's atmosphere (21 percent) is necessary for our respiratory systems. The percentage is maintained because trees, algae, and bacteria use carbon dioxide, which humans exhale as respiratory waste, to produce oxygen that replenishes the atmosphere. Another example of such a feedback system is the radiation of heat from the sun, which the planet absorbs and reflects; either action depends on the number and kind of living things on Earth's surface.

Lovelock named his theory Gaia after the ancient Greek primordial Mother-goddess. The name added appeal to the New Age community and its dual fascination with environmentalism and religion. Lovelock attempted to distance himself from those who adopted his hypothesis as proof of an omnipresent Earth deity. In 1988, however, he wrote a second book on Gaia for a lay audience. In this work he occasionally implied that Gaia was conscious; indeed, Gaia might compensate for people's tendencies to pollute by gradually eliminating humankind.

Lynn Margulis, a distinguished cellular biologist, boosted the credibility of the Gaia Hypothesis by joining Lovelock's project in 1970. However, many scientists, such as Daniel Botkin, were ambivalent about Gaia theory because of its religious undertones. Others, such as James Kirchner, pointed to logical discrepancies. Lovelock's statement that Gaia seeks a steady state, an unadapting ecological balance, appeared to contradict the processes of evolution. Further, if "Gaia" is just an overall term for Earth's feedback systems, then the Gaia Hypothesis is nothing new. Today, the debate still shows how personal interpretations can exist and compete in the absolutist world of science.

began in 1947, groups arose that reinvigorated the occult movements and began to reinterpret the spiritual masters of the occult movement as space commanders who transmitted messages to mankind through their human contacts or abductees.

In the 1960s, with the changed U.S. immigration law, the presence of Asian peoples increased, as did the influence of Eastern religions. While the various metaphysical movements of America bolstered their legitimacy with Asian sources and absorbed the ritual practices of Eastern religions, the movements simultaneously began to absorb the revived spiritual traditions of Native Americans. New Age movements incorporated shamanic ritual and seized upon Native American spirituality to develop an emphasis on nature, inherited from Transcendentalism, into a protoenvironmentalism. This renewed focus upon the macrocosm of the earth provides the conceptual foundation for some New Agers to espouse belief in Gaia, the Earth Goddess/Mother. The accompanying hope for planetary healing through human effort is but one manifestation of a persistent millennial theme in New Age religions.

Kejawen—Religious Resistance on Java

Islam is the religion of the majority of Indonesians today and is especially entrenched on the

island of Java. However, many Javanese have continued to hold to a set of indigenous beliefs termed *kejawen* (Javanese science) that combine animist, Hindu, and Islamic elements. Of central importance in this system of beliefs are traditional ceremonies aimed at communicating with and placating the spirit world. Powerful spirits are held to live at various points in Java, including mountains, the sea, and gravesites. *Kejawen*, however, is not an organized religion and possesses little in the way of clergy or a central scripture. Its followers do recognize a type of shaman (*dukun*) and venerate certain texts and folktales. Nor has *kejawen* directly rejected Islam, but it has, in fact, existed in symbiosis with Islamic practices.

At the beginning of the fifteenth century Java was dominated by the Majapahit kingdom. While the court practiced a local version of Hinduism and numerous temples dotted the landscape, the population retained many animist customs. By the middle of the century, however, this powerful Hindu empire was in decline. Muslim city-states emerged on the island's northern coast, and Islam slowly spread from these outposts into the interior. The emergence of *kejawen* as an identifiable set of beliefs is related to conversion to Islam, a process that continued until perhaps the end of the eighteenth century.

The form of Islam that developed in Java's interior blended elements common throughout the Islamic world with indigenous belief in the spirit realm and a reverence for local royalty. To this day, Javans hold that the Sultan of Yogyakarta possesses supernatural abilities and enjoys an intimate relationship with Loro Kidul, a mythical marine goddess. The population, while nominally Muslim, devoted itself to appeasing the spirit world through modest ceremonies conducted with the help of shamans and exorcists in response to life crises. Importance was also placed on pilgrimages to holy places situated in the mountains and forests. Little attention was paid to regular prayer or study of the Quran. *Kejawen* could be seen as a type of religious belief and practice that goes beyond this form of Javanese Islam. Islamic elements are downplayed in favor of indigenous elements. This has led some to claim that *kejawen* is not in

fact Islamic at all but instead constitutes a separate religion.

Some Javanese have embraced the idea that *kejawen* is indeed distinct from Islam and have started to form groups to practice traditional spiritual exercises. Many of these groups are organized around charismatic teachers and have come to attract a national or even international following. In the 1970s these groups started to look for official recognition. In the wake of the 1965–1966 suppression of the supposedly atheistic Indonesian Communist Party there was increasing importance placed on choosing an official religion, with the government establishing a separate department to oversee religious affairs. Every citizen had to choose from one of the official religions and note this on their identity card. Some felt that all the available choices were foreign religions and that official recognition should be granted to at least one indigenous faith. Such sentiments were given some encouragement from within the Indonesian government. It was rumored that President Suharto and some in his circle were in fact *kejawen* practitioners.

Efforts to make *kejawen* an official religion have petered out, as many Javanese are embracing a more self-conscious Islamic identity. With the trends of urbanization, modernization, and globalization there is less interest in folk beliefs associated with a rapidly disappearing rural world. However, when the volcanic Mount Merapi became active again in 2006, it was to the mountain's traditional guardian, a hereditary shaman appointed by the sultan of Yogyakarta, rather than to government seismologists that residents turned for advice on when to evacuate. *Kejawen* is a reminder that religious beliefs and practices perhaps never really disappear. Islamic beliefs and practices arrived in Java 500 years ago but had to adapt to local conditions and recognize the power of local belief in order to take root in a complex society strongly influenced by animistic traditions.

➤ CLIFFORD GEERTZ—*SANTRI*, *PRIYAYI*, AND *ABANGAN*

The nature of *kejawen* is connected to a terminology devised for the study of Javanese religion by American anthropologist Clifford Geertz (1926–2006). He divided Javanese society into three streams: *santri*, *priyayi*, and *abangan*. Although all three groups identified themselves as Muslim, they had very different ideas as to how this religion should actually be practiced. *Santri* took their commitment to Islamic regulations seriously. Prayer, fasting, and the pilgrimage to Mecca were all central elements of *santri* life. The *priyayi* stressed refinement and the cultivation of inner peace and spiritual power through meditation, art, and mysticism. Some critics have questioned whether the *priyayi* is really a valid religious category at all and is not better understood as a sociological label for the minor Javanese aristocracy. The *abangan* stream was that of the rural peasant whose religious outlook was a syncretism that combined animism with Hinduism and Islam. The core ritual of the *abangan* variant was the *slametan*, a ritual intended to appease hostile spirits. *Kejawen* could be seen as simply a more defined version of the *abangan* stream, with more emphasis placed on local traditions and a more obvious rejection of some of the Islamic practices associated with the *santri*. Much has changed since Geertz conducted his fieldwork in the late 1950s, especially as Javanese rural society has come under increasing influence from a larger Pan-Indonesian society. Many Javanese have abandoned *abangan* or *kejawen* identities in favor of more self-consciously Islamic ones.

Global Ashrams

In the popular imagination, the word *ashram* (anglicized form of Sanskrit *ashrama*) evokes images of a peaceful and serene natural setting where persons in search of the ultimate spiritual goal flock. In Classical Hindu literature, written mostly in Sanskrit, ashrama has two meanings. One meaning of ashrama in the ancient literature is connected with a location, a place. The other meaning is a more technical one that is connected with modes or stages of life.

The ashram was an important feature in the development of Hindu reform movements that began in the late nineteenth century in India. These movements reached back to India's long religious history and remodeled ancient tradition in the style of Western missions. Movements such as those led by Swami Vivekananda (1863–1902), Swami Chinmayananda (1916–1993), and Swami Shivananda (1887–1963) of Rishikesh spread throughout India and beyond, with a number of them now located in Europe and the Americas.

Ashrams, both inside and outside India, show great variety and complexity. Structurally, an ashram may consist of a small building with a few rooms, where devotees may come to obtain *darshan* (sight of the deity) and spiritual education. The daily routine of an ashram is exemplified by Swami Shivananda's daily routine, which consisted of evening talks and question and answer periods with disciples. Evenings would also include recitation of religious texts and singing of devotional songs (*bhajan*s).

Many ashrams stress a commitment to social outreach and services, such as running local schools, medical clinics, or training centers. After the establishment of the Divine Life Society, Shivananda's mission established hospitals, annual outpatient camps for persons in need of surgical treatment, villages for lepers, and vocational training centers for low-caste women. The Ramakrishna Mission established a dispensary in Bhuvaneshvar, Orissa, in 1920 to provide free medical treatment in both traditional Ayurvedic medicine and modern Western medicine. In addition to outreach programs that provide medical services, BAPS Swaminarayan Sanstha provides educational programming ranging from religious

education to educational programs to encourage computer literacy.

The appeal of the modern ashrams, both inside and outside India, can be traced to features that reach back to the ancient forest ashram visited by heroes and gods of Hindu religious texts. At its core, the ashram remains an ideal, an island of peace in the midst of the chaos of the world. Modern ashrams continue to focus on this key ideal as a selling point. The Shivananda Yoga Vedanta Centers in India, Europe, the Middle East, and the Americas emphasize this feature of ashrams with their yoga vacation programs. These vacations provide the intense experience of the ashram as a way to recharge. Individuals are attracted to the ashram because they are in search of religious truth and an escape from the madness of the world.

Religion and the Arts since 1945

Religious traditions have had long and difficult relationships with arts. Religious movements have affirmed the place of icons and images, and other movements have destroyed images in the name of protecting the faith. World religions, from the Abrahamic faiths of Judaism, Christianity, and Islam to Hinduism and Buddhism, have all appropriated art and images in myriad ways throughout their histories. With the advent of modernism and abstraction in the twentieth century, religious imagery was not as obvious as it once was in the arts, but religious belief still found expression in art forms.

In the Abrahamic faiths, there have been injunctions against visual representations of God,

but Christians, Jews, and Muslims still produce their own versions of visual belief. Christian art after 1945 might be considered lacking when compared to previous historical periods, but symbolism of this faith appears in art forms ranging from Abstract Expressionism to new renderings of Jesus as black, female, Asian, and so on. Religious imagery has also been co-opted by artists with a more secular vision or by those who seek to use religion as a revolutionary element in art. In the 1990s, there was much controversy over Chris Ofili's *The Holy Virgin Mary*, in which Mary was created partially out of dung, and Renée Cox's *Yo Mama's Last Supper*, in which she poses naked as Christ. Both artists pressed the boundaries of what the relationship between art and religious imagery is in the post-modern age.

On the other hand, since 1945 many Jewish artists have grappled with the impact of the Holocaust. Jewish art might seem like an anomaly because of the Hebrew Bible's injunctions against idolatry and rabbinic teachings that any representation of the divine is reductive. Yet throughout their history, Jewish people have made artifacts, art, and architecture imbued with spiritual intent. In the modern era, Barnett Newman in particular attempted to understand the world post-Holocaust, and his abstract paintings attempted to repair the world (*tikkun olam*). His paintings were large fields with a thread of different color running down the center, and it was his attempt to reorder a world that was broken after World War II.

Islamic art has retained a focus on calligraphy, which leads to abstraction rather than figuration. This art contains passages from the Quran as well as geometric and floral patterns because figural representation, icons, and idolatry are forbidden with Islam. In 2001, Taliban leader Mullah Mohammed Omar delivered an edict against non-Muslim graven images, and thus the Taliban set about destroying ancient Buddha sculptures in Afghanistan. Islamic art has still flourished despite this injunction. Following the Iranian Revolution in 1979, some Muslim artists have used their art for political and religious commentary in abstract forms to protest and to affirm the revolution.

➤ RELIGION AND THE ARTS

(UNESCO/F. Riviere)

In early 2001, Taliban leader Mullah Mohammed Omar presented an edict in which non-Muslim graven images were to be destroyed as idolatrous. With explosives and tanks, the Taliban reduced two gigantic statues of the Buddha in the Bamiyan Province of Afghanistan to rubble. The Buddhas were possibly crafted between the third and fifth centuries CE, and they were located at the heart of what had been the Silk Roads. Bamiyan was also a Buddhist center for at least 500 years. The international community reacted in horror to the destruction of these artifacts, with some Muslim leaders also condemning Omar's actions.

—Kelly J. Baker

Hinduism and Buddhism have long relied on visual cues in religious practice. In Hinduism, *darshan*, the act of religious seeing, is crucial for the experience of the divine. Images contain the divine in this tradition, and thus religious imagery is used as a part of worship. From shrines to mass-produced images, the arts are vehicles for the divine. Images also are used in Buddhism to aid in meditation to focus one's mind. Images

and statues of the Buddha proliferate as examples of his life as well as a means for religious devotion. For both Hinduism and Buddhism, the arts have served in religious practice for centuries. For all of these traditions, the arts express both the individual artist and the larger community's faith, beliefs, and histories.

The Black Muslims

"Black Muslim" was a term given to the African American Muslims by historian C. Eric Lincoln in the 1950s. These Muslims were generally the followers of Elijah Muhammad, a charismatic leader who succeeded Wallace Fard, the founder of the Lost Found Nation of Islam in the Wilderness. When Fard disappeared in 1934, Muhammad became the leader of the Nation of Islam and turned it into a black nationalist movement. Under Muhammad, the group preached the supremacy of African Americans over white Americans. Muhammad encouraged blacks to be free from a slave mentality, to reject drugs and Christianity, and to be financially independent. In addition, he urged African American men to respect black women and the ethics of hard work.

Malcolm X, Louis Farrakhan, and Warithu Deen Mohammed also played important roles

in the Nation of Islam. After his conversion in the late 1940s, Malcolm X recruited many black youths into the Nation of Islam through his relentless efforts and charisma. He devoted much of his life to the Nation of Islam but was assassinated in 1965 after rejecting Muhammad's leadership and teachings after making the hajj to Mecca and coming to understand the nature of traditional Islam. When Muhammad died in 1975, his son Warithu Deen Mohammed succeeded him and, condemning many of his father's ideas, reformulated the group under the new name American Muslim Mission. He turned the group toward mainstream Islam and away from separatism and racial hatred. In 1985, Mohammed decentralized his group and asked each imam to lead his community. In October 2003, he resigned from the leadership of the American Muslim Mission.

Farrakhan broke away in 1977 from Mohammad's American Muslim Mission to revive the Nation of Islam and some of its separatist philosophy. Farrakhan remains the leader of the group today. Both the Nation of Islam and members of Imam Mohammed are very active in the black community. Prison is one of the recruitment sites for both groups. The public perceive the Nation of Islam as violent, but that perception has changed since the 1980s, as they have participated in politics and established their own schools and businesses and an independent outlook.

■ Introduction: Age of Ideology

The very notion of ideology (or of a society's self-justifying belief system) has always implied that it was a limitation to be overcome. In the nineteenth century, Karl Marx and Friedrich Engels noted that what was regarded as culture—whether thought, the arts, or religion—was simply sugarcoated expressions of harsh underlying economic realities. Economics, in their eyes, forged belief systems. At the same time, anthropologists had begun to study and define the presumably exotic ways and beliefs of primitive peoples, keeping ideology, whatever its origins, at a safe remove. As the anthropologist Clifford Geertz remarked in *The Interpretation of Cultures* (1973), “I have a social philosophy; you have political opinions; he has an ideology.” By the early twentieth century, the successes of socialism and communism and their fundamental conflict with democracy and/or capitalism guaranteed ideological debate and battle.

The Cold War brought both an intensified ideological clash and a desire in many to step above the ideological trap. Following World War II, sociologists, political theorists, writers, and public intellectuals puzzled over how extreme and inhumane belief systems were nurtured and manipulated by groups such as the National Socialists (Nazis) in Germany, the fascist regimes in Spain and Italy, and the Stalinist and later Maoist regimes of the communist world. Concerns over the power of propaganda channeled via media interlocking with other systems of social control animated novels such as George Orwell's *Animal Farm* (1945) and *1984* (1949). Other intellectuals, including the psychoanalyst Eric Fromm, explored concerns about the dangers of conformity in the so-called free nations. Fromm argued in *Escape from Freedom* (1941) that totalitarian movements could be accounted for by their fulfillment of individual psychological needs, making them appealing to all.

At the same time that mass culture theorists fretted over the possibility that something akin to totalitarianism lurked behind the conformity found in the free market liberal societies of the

West, the Cold War struggle between the United States and the Soviet Union only intensified, with each side (whether communist or capitalist) claiming absolute truth and maximum benefit for their own socioeconomic system. Both sides demonized the other and painted the other as imperialist, bent on world conquest and control. Yet within each side were differing ideological camps, whether Stalinism, Maoism, Leninism, and Trotskyism on the communist side or the many shadings of belief under liberal capitalism in the West (from conservative to liberal). Both sides had converts and apostates renouncing their former views. For example, as part of anti-communist discourse, writers such as Arthur Koestler and Andre Gide, who had once held communist beliefs, renounced that faith in the anticommunist work *The God That Failed* (1949).

The intensity of the anticommunist bent in the West and the anti-American bent in other parts of the world and their inevitable contradictions in international and domestic actions ultimately fostered domestic dissent. In the 1960s, young people, nurtured on critiques of conformity and mass culture, questioned the tenets of liberal democracy and often embraced, in wild extreme and perhaps with a shopper's zeal, such alternative ideologies as Maoism with its seemingly exotic empowerment of the peasantry engaged in noble struggle. Dissenters in the Soviet Union chafed under the surveillance of a police state and its repression of free discourse.

Philosopher John Dewey, over a long career, analyzed, explained, and defended liberalism as an evolving philosophy that was premised not only on the development of a free market and free exchange of thought but also on the personal development of all citizens, which implies social protections such as a rejection of unfettered capitalism. In the West, the conservative movement regrouped in the 1950s through the 1970s and briefly became the main current with the ascent of neoconservative thought, which encouraged deregulated national markets, and the linking of global markets with an accompanying erosion of labor and social welfare. Curiously,

liberalism, which Dewey labored to define as all that was noble about capitalism, during this period became and for many remains a dirty word.

Much of the poststructuralist and postmodern thought that emerged in Europe from the 1960s on was, once again, in reaction to the excesses of the Cold War and a growing distrust of authority and expressed an attempt to escape ideology and the limits of subjectivity (or personal consciousness ideologically conditioned). While the collapse of the Soviet Union implied for some an end to history and ideology, it also revived nationalist ideologies (such as Greater Serbia). Yet for others, recent decades have been a call to invent one's own ideology and reinvent history, resulting in the many conspiracy theories posted on Internet sites among the like-minded with views that span the political and philosophical spectrum.

—*Fred Nadis*

Cold War Ideology

Since 1945, the divisions created by the global Cold War gave rise to a variety of new political ideologies created in response to the emergent new world order built in the ruins of World War II and the bygone era of European primacy in world affairs. The ideological world views that emerged during this period, while building on previous frameworks, developed specific characteristics that addressed current political, social, and economic issues of the latter half of the twentieth century. The capitalist liberal West under U.S. leadership and the communist authoritarian East under Soviet (and later Chinese) leadership accused each other of being a threat to world peace, attempting to colonize the world, and dispersing agendas and agents to create regional instability in Southeast Asia, the Middle East, Latin America, and Africa.

The postwar capitalist West, characterized by liberal democracies seeking to counter the spread of global communism, sought to re-create the world in its image, espousing economic prosperity and personal freedom while demonizing the communist world under the leadership of the Soviet Union. Amid the destruction created by World War II, the United States assisted in the rebuilding of Western Europe (and the European

Economic Community) through the Marshall Plan and its support for liberal democracy to counter communist advances. In the United States, Western Europe, and Australia, new definitions of liberalism and conservatism addressed postwar domestic social concerns (among them issues of class, race, and gender) and foreign policy objectives (Cold War, decolonization, global trade). With an intense distrust of both the Far Left (Stalinists, anarchists, and communists) and the Far Right (Neo-Fascists, paleo-conservatives, Segregationists), these new sociopolitical movements embraced a *modus vivendi* that supported the welfare state, statist public policy, and the advancement of rights for minorities, women, and other disenfranchised groups. However, specific ideological views divided the political spectrum throughout the West on how best to approach these changes in creating a more egalitarian society. Moreover, excesses in Cold War strategy (the Algerian War, the Vietnam War, CIA coups in the developing world) further divided the ideological camps within the West, yet fears of Soviet world domination shaped ideology and many of the domestic and foreign policies of the United States and its allies in global affairs.

The Communist Bloc (Eastern Europe, the Soviet Union, China), which straddled much of Eurasia from the mid- to late-twentieth century, was characterized by the internal drive to industrialize to better compete with the capitalist world and quell the external threat (the imperialist capitalist West) to the advancement of the socialist experiment. These two forces shaped the ideological development of Marxist-Leninist ideals in the immediate postwar socialist world, albeit sometimes in conflict with each other (i.e., Khrushchev's so-called thaw in 1954 was in direct conflict with Stalinist diehards across the socialist world). However, Soviet excesses in Hungary (1956) and Czechoslovakia (1968) created rifts in the socialist world, leading to the emergence of divergent roads to socialism (goulash socialism, Titoism, Maoism, and Third World revolutionary movements). Neo-Marxist intellectuals and revolutionaries denounced the authoritarian approach (Stalinism) to the socialist project and suggested advancing the plight of the oppressed throughout the world to best engage the alleged capitalist enemy (most notably

the United States and its European allies) and its new tools of imperialist conquest (the World Bank, the International Monetary Fund, and G-8). These neo-Marxist ideals resonated with much of the newly decolonized developing world (sub-Saharan Africa, Oceania, Southeast Asia) and underdeveloped peripheral regions (Latin America, East Asia, and the Middle East) seeking to extricate themselves from the neocolonial power relations (such as Zionism, globalization, and U.S. global presence) vis-à-vis the West. Often, this led to soured relations with the Soviet Union, which espoused more moderate courses of action in terms of its national interests. Nonetheless, members of this bloc could all agree on the alleged imperialist economic ambitions of the United States, shaping a common ideology.

On both sides of the divide, Cold War ideology inflected not only policy and propaganda but also culture and thought.

Modern Liberalism

In the decades following World War II, the ideology of liberalism took on different meanings throughout much of the world, resulting in divergent trajectories from a common European ideological origin. The liberal democracies of Western Europe, North America, and Oceania, which, in league with the Soviet Union, confronted the fascists during World War II, now found themselves engaged in the global Cold War with this former ally, severely affecting domestic politics. Liberal politicians sought desperately to differentiate themselves from the Far Right (fascists) and the Far Left (communists) and in so doing altered the ideological composition of liberalism. Throughout Western Europe, Latin America, and much of the postwar decolonizing world (sub-Saharan Africa, East Asia, the Near East), liberalism represented a European

➤ BRAINWASHING AND THE COLD WAR

Following the Korean War, accusations that the Koreans and the Chinese had used brainwashing techniques on American prisoners of war (POWs) surfaced, leading to various studies on the issue in the United States. In the mid-1950s studies by Robert Jay Lifton and Edgar Schein concluded that brainwashing had a significant effect on POWs, as the Chinese had practiced coercive persuasion to induce behavior modification. Practices such as sleep deprivation, dehumanization, and harassment served to make prisoners confess, make anti-American statements, or strongly adhere to socialist ideology. Many of these tactics had been used earlier in the Soviet Union during the show trials and purges of the 1930s. Popular fear of brainwashing was reflected in the film *The Manchurian Candidate* (1962). The film depicts a communist plot to brainwash a former Korean War POW to turn him into an assassin and thus ensure the election of a communist puppet to the U.S. presidency. While there was a genuine fear in the United States that the Soviet Union and China were engaged in brainwashing, these fears were reciprocated when rumors of the Central Intelligence Agency (CIA) engaging in similar tactics across the world surfaced from time to time in the 1960s and 1970s.

—Abraham O. Mendoza

ideology mostly identified with traditional pre-war capitalist elites who recognized the authority of representative government while remaining suspect of its encroachments on the market and the rights of the individual. However, in the United States, liberalism in the postwar period shifted from an ideology that identified itself with the broad needs of the nation and the modern economy (Franklin Delano Roosevelt's New Deal welfare state) to one that sought to extend civil rights to minorities, women, and other excluded groups (as in the Great Society, the War on Poverty, Affirmative Action, and so on).

West European liberalism in the postwar period, embraced by the Christian Democratic movements in France, Germany, and Italy and working against the communist threat at the polls, sought to rebuild the European state and

➤ POLITICAL CORRECTNESS

Political correctness (abbreviated as PC) is a term that began on the political Left and was meant to evaluate public discourse so as to eliminate discrimination against marginalized or disadvantaged groups in society. It originated as a Marxist-Leninist term delineating the correct party position. In the 1960s, the New Left in the United States began to utilize the term as a way to establish the correct definition of group identifications in public discourse (for example, concerns over using the terms “Afro-American” or “black,” “Mexican American” or “Chicano” or “Latino/a,” and so on). Gradually, it became a linguistic tool geared toward shaping ideas and words in public discourse (sexist language, racist epithets, religious biases), with the objective of making the public aware of unconscious biases and to discontinue the use of expressions found offensive by marginalized groups. It has gradually expanded throughout much of the world as a way to transform existing biased attitudes toward women (Ms. instead of Miss), immigrants (British blacks in the United Kingdom), and other marginalized groupings (i.e., homosexuals, transgender, and the disabled).

Humor based on the excesses of PC language originated both in the political Left and among conservatives. For example, the bumper sticker “Nuke the Whales” became common in the 1970s as a response to the holier-than-thou attitude that emanated from PC environmentalist and anti-nuclear weapons circles. Criticism of PC on the part of libertarians, conservatives, advocates of free speech, and right-wing radio talk shows in the United States is still widespread. Much of this criticism alleges that PC language is a form of censorship that restricts rather than liberates individuals, constraining them to act and speak in a specific way through coercion and social controls. In this regard, PC is often compared to George Orwell’s concept of newspeak as presented by the bureaucracies and propaganda wings of governments. Furthermore, divisions over the proper usage of terms, even within many of these supposed marginalized groups, illustrate the complexity of establishing a consensus over a proper PC lexicon.

—Abraham O. Mendoza

economy under U.S. tutelage (i.e., the Marshall Plan and the North Atlantic Treaty Organization [NATO]) and with the nascent European Economic Community (EEC). While Europe’s liberal leaders, favoring individual rights and free markets, were resistant to the idea of the welfare state, they reluctantly worked with socialists due to their apprehension of communists coming to power in this period of political and economic vulnerability. Many of these European liberals (Konrad Adenauer in West Germany, Alcide De Gasperi in Italy, and Robert Schumann in France) had been influential in government before the war as liberals of the prewar vein. In the immediate postwar period, these liberals viewed a wider European structure, or the EEC, as a viable way to integrate their economies and their political structures, maintaining the liberal definition of representative government as an ideal. However, as European politics turned sharply toward the socialist Left in the early 1960s, many of these liberals found themselves out of power. In later decades, liberalism in Europe found itself out of the mainstream of politics, still advocating decentralized representative government (as opposed to the centralized welfare state) and neoliberal economic policies, items that had been gradually discredited in continental European politics for decades (except in the United Kingdom, where neoliberalism was embraced by both Conservative prime minister Margaret Thatcher and Labour prime minister Tony Blair). In Western Europe, however, both center-right and center-left coalitions embraced the welfare state as *modus vivendi* between capitalism and communism, relegating ideological liberalism to the margins of political life.

Much of Latin America (except Brazil) had a common liberal tradition harkening back to the Wars of Independence from Spain in the early nineteenth century, defined by support for representative government, secularism, and egalitarian ideals. In the period following World War II, liberalism was embraced by pro-Western Latin American elites to maintain their hold on political and economic power, much to the dismay of the workers and peasants. The influence of socialism and communism (particularly Maoism) in Latin America was particularly strong, especially after the successful Cuban Revolution of

Fidel Castro (1959). From the 1960s to the 1980s, CIA-supported right-wing military coups (Argentina, 1976; Chile, 1973; Nicaragua, 1984) seeking to stem the socialist and communist surge in domestic politics eventually displaced the traditional hold of liberals in power. Widespread resentment against alleged U.S. hegemony in the region has provided socialism with tremendous political capital, leading to the successes of its more recent proponents in Brazil, Venezuela, and Bolivia.

In many of the decolonizing regions of the world, such as the Near East, South Asia, and sub-Saharan Africa, liberalism was embraced by colonial elites espousing independence from European colonialism. However, liberal conceptions of representative government proved to be quite fragile given the ethnic divisions that characterized the various postcolonial states, as seen in the partition of India (1947) and its effect on Pakistan (1971), Kenya (1991), and Iraq (2003). The British Westminster system of granting independence to colonies with representative parliaments while maintaining their economic dependence on the United Kingdom (seen by critics as the roots of neocolonialism) severely undermined efforts to legitimize liberalism abroad. Some of these early experiments at liberalism in Africa and Asia eventually gave way to oppressive right-wing military rule (Kenya, Egypt, South Korea, and Pakistan). Communism (particularly Maoism) and socialism, in addition to Islamic fundamentalism (primarily in the traditional lands of Islam in North Africa, the Near East, and Central and South Asia), have had significant influence in these regions, where traditional liberalism remains suspect as a form of Western infiltration along with its neoliberal economic policies.

In the postwar United States, liberalism transformed itself from an ideology advocating the gradual expansion of the national welfare state (the New Deal) to that of one espousing the extension of civil rights to women, minorities, and other disenfranchised groups, particularly associated with the realignment of the Democratic Party under Lyndon B. Johnson. Shaped by the political thinking of longtime advocates of social reform such as John Dewey as well as the political radicalism of the New Left and civil rights

organizations, liberalism in the 1960s embraced multiculturalism, identity politics, and policies advancing progressive social reform. During Johnson's presidency, liberalism transformed from an ideology advocating statist social reform to alleviate poverty through wealth distribution (Great Society, civil rights, War on Poverty, etc.) to one actively supporting the radical movements of the late 1960s (protests against the Vietnam War, minority power movements, women's rights, etc.) emphasizing greater social equality. However, attacks from the resurgent political Right from the 1970s to contemporary times moved many liberals such as President Bill Clinton to the center, seeking to break away from the previous flirtation with the progressive Far Left. Contemporary U.S. liberalism reflects traditional support of the central government in alleviating socioeconomic disparities through the expansion of the welfare state, along with further expansion of the civil rights of disenfranchised groups, while at times supporting centrist middle-of-the-road compromise positions regarding neoliberal economic policies (North Atlantic Free Trade Association [NAFTA], 1994) and values policies (e.g., the infamous "Don't Ask, Don't Tell" law concerning gays in the U.S. military that passed in the U.S. Congress in 1993).

In Australia, traditional liberalism has succeeded in surviving through the political success of the Liberal Party in postwar decades in spite of the expansion of the welfare state in the postwar period under Labour control of the federal government. However, with its support of U.S. foreign policy, neoliberal free trade policies, and decentralized government, the Liberal Party has found itself under scrutiny by the Labour opposition in recent years.

Neoconservatism

Neoconservatism is a U.S. political ideology that developed in the decades following the end of World War II that advocates an international free market economy and a fervent anticommunist foreign policy (first directed against the Soviet Union until 1991, now against China) in tandem with the global spread of democracy through U.S. military power. The term was first used in 1972 by Michael Harrington as a derisive term to identify a group of self-described liberals who were really conservative ex-liberals. The movement developed out of a collective group of Jewish New York intellectuals who had previously been fervent devotees to President Franklin Delano Roosevelt's New Deal in the late 1930s and early 1940s. It later attracted some liberals, those mostly disenchanted with the liberalism of the Democratic Party of Lyndon B. Johnson and its flirtations with the New Left of the 1960s. At this time, the neoconservatives developed a political philosophy that embraced fervent anti-communism and the spread of democracy around the globe, putting them at odds with both the Republican Party (suspicious of them as liberals) and the Democratic Party (who viewed them as centrist liberals deviating from the progressive wing). With the election of President Ronald Reagan in 1981, neoconservatives switched en masse to the Republican Party and helped shape its foreign policy objectives in the last days of the Cold War and well up to the post-September 11, 2001, conflicts: the War on Terror and the Iraq War.

The intellectual roots of neoconservatism lie in a group of Jewish intellectuals centered in City College in New York City in the 1930s. During this time, this small group became increasingly supportive of Roosevelt's liberal policies, many of them enacted in the late 1930s and known collectively as the New Deal. Influenced by Trotskyite ideals, trade unionism, and the New Deal, Lionel Trilling, Irving Kristol, and Norman Podhoretz, among others, developed what was to later become the ideology of neoconservatism. Following the 1939 Nazi-Soviet Pact, the divide in the progressive ranks between the supporters of Soviet-backed communist organizations and other leftists led a small group of Jewish

intellectuals to split from a larger group of communist-affiliated intellectuals. In the midst of World War II, this small group of anticommunist liberals maintained their autonomy from the progressive Far Left and its unwavering support for Stalinism while remaining supportive of U.S. efforts abroad to liberate Europe and East Asia from the Axis forces and active participants in the U.S. Democratic Party.

In the late 1940s and early 1950s in the midst of the Cold War, the neoconservative coterie remained among anticommunist centrist liberals staunchly on the side of the United States while able to denounce those who implied that all liberals were Soviet sympathizers, especially Senator Joseph McCarthy. Now working as journalists, editors, and publishers, many of them were able to voice their political positions, largely through the publications *Commentary*, *The Public Interest*, and *Dissent*. They maintained their ideological differences with the Far Left progressive liberals (some still supportive of Stalinism until 1956), who cast all anticommunists as McCarthyites and traitors to liberalism.

During the 1960s, as John F. Kennedy and then Lyndon B. Johnson unleashed a vast set of social reforms and programs aimed at ending poverty and redistributing wealth among the less fortunate (New Frontier, Great Society, War on Poverty), liberals in the United States responded with enthusiasm and united themselves to the cause. However, in the midst of the massive social changes brought about by the extension of civil rights legislation, widespread protests against the Vietnam War, ubiquitous criticism of Israel after the 1967 Arab-Israeli War, and the growth of the counterculture in U.S. society, the anti-communist liberals became wary of what they considered to be the appeasement of the New Left (student radical organizations, civil rights activists, red-diaper baby boomers) by the Old Left (Great Society liberals) during the turbulent late 1960s. The flirtation of the Democratic Party with what were then considered anti-American radicals led anticommunist liberals to openly criticize the liberal establishment of the party currently in power in the late 1960s. By 1972, this breach led to this group being labeled neo-conservatives, or liberals without a home on the Democratic Party's liberal and left wings. How-

ever, they maintained their place, albeit an uncomfortable one, in the ranks of the Democratic Party.

In the 1970s, many neoconservatives critiqued the enactment of civil rights-based quota programs in educational and occupational programs to ensure equitable racial integration. Many neoconservatives saw this as a breach of the intention behind civil rights, and some of them, as Jews, were shocked to see quotas, something used in the past to limit the amount of people in a given occupation (primarily Jews), now being used to accommodate people's entry into occupations and educational institutions. Moreover, President Richard Nixon's policy of détente vis-à-vis the Soviet Union and his opening of China alarmed neoconservatives, who saw this as a form of appeasement of global communism. They were also critical of the Nixon administration's support of pro-American anticommunist dictators in the developing world. In this fashion, they were alienated by both the political Left and Right, opposed to affirmative action programs and its quotas and what they perceived as reverses in U.S. foreign policy in Vietnam and against the Soviet Union and China under Nixon. Anti-Soviet Democratic lawmakers such as Senator Henry "Scoop" Jackson and Republican hawks such as Ronald Reagan, fervently against Nixon's policies, were backed by previously reluctant neoconservatives.

The election of Reagan as president of the United States in 1981 finally allowed the neoconservatives to join the Republican Party, as he advocated a more aggressive policy against the Soviet Union than his predecessors. While some neoconservatives felt ill at ease with the emerging New Right and its alignment with evangelical pro-life Christians (the Moral Majority), they felt that Reagan was a better fit than the evanescent liberal Left. While this support of Reagan meant the slow erosion of social programs enacted under the Great Society, which many neoconservatives had supported wholeheartedly, it also meant the extension of U.S. military power in confronting global communism, which did eventually come crashing down between 1989 and 1991 due to external and internal factors.

By 2007 many neoconservatives occupied positions in conservative think tanks (such as the

➤ BLAIRISM

British prime minister Tony Blair brought the Labour Party into power with a landslide victory in the 1997 general election. He was the Labour Party's longest serving prime minister and the only person to have led the party to three consecutive general election victories. (British Embassy)

Blairism refers to support for the policies of Prime Minister Tony Blair and his New Labour policies in the United Kingdom from 1997 to 2007, which included an Atlanticist foreign policy (which critics alleged was an unbending compliance with U.S. foreign policy in world affairs), greater European integration, and economic policies of privatization similar to those of Margaret Thatcher. Blairism, or New Labour, was a centrist position by the British Labour Party, developed to attract probusiness and pro-free market

Conservative voters while maintaining the traditional Labour core.

Maintaining a centrist position was not without its critics, who alleged that this was a betrayal of the core values and previous platforms of the Labour Party, which had historically been the stalwart supporters of both the British welfare state and labor unions. This is similar to Democratic U.S. president Bill Clinton's embracing of unhindered free trade economic policies and curtailing of social programs in order to appeal to center-right probusiness fiscal conservatives in the mid-1990s. This precarious alliance at the political center, while expedient in gaining voters in the short term, alienated both Blair and Clinton from both the political Left and Right in their respective countries.

—Abraham O. Mendoza

American Enterprise Institute and the Hoover Institute) as leaders in the presidential administration of Republican George W. Bush and as shapers of public policy and foreign affairs. Their vision of spreading democracy abroad and quelling global communism (and now global Islamo-fascism) had been extended to establishing democratic regimes in the Near East and Central Asia. In the post-September 11 world, they actively promoted regime change throughout this volatile region, advocating the global War on Terror and current Iraq War. However, their willingness to embark on extensive deficit spending on these wars pitted them against fiscal conservatives in the Republican Party as well as libertarians opposed to their support of increased government bureaucracy and increased surveillance of citizens (PATRIOT Act, Department of Homeland Security). Yet neoconservatives continued to find common ground with social conservatives on their foreign policy objectives considering the War on Terror a moral crusade in its extension of U.S. democratic values abroad.

Communist Ideology—Third World Revolution

At the end of World War II as the European empires throughout much of the world began to dissolve, the influence of Marxism and its anti-imperialist rhetoric became widely popular among the colonized masses. The experience of the war, with the removal of the defeated colonial authority by the Axis and with the work of the resistance movements in response run by the colonized themselves, did much to discredit the British and French throughout their imperial dominions. The immediate post-Cold War antagonism between the United States and the Soviet Union, along with the People's Republic of China

(since 1949), made the leadership of many newly decolonized nations choose communist support in the face of the potential indirect rule of U.S. global hegemony, either through the international organizations of the International Monetary Fund (IMF) or the World Bank or through the direct U.S. support of right-wing pro-Western dictators. Many of these communist movements had to take to the countryside to fight against the imperialist oppressor through revolutionary tactics (guerrilla warfare) to break the will of an otherwise superior military force, relying on the support of the Soviet Union and/or China.

From the 1950s through the 1970s, as decolonization proceeded throughout much of East and South Asia, North Africa, sub-Saharan Africa, and the Near East, the influence of communism resonated throughout many of the newly independent nations. British policies of decolonization emphasized placing “responsible” representative government in power (the Westminster system) along with secure economic ties that placed the new nation securely under the economic control of the United Kingdom. Communist factions (particularly in Malaysia) in the newly created British Commonwealth of Nations (a loose coalition of former British colonies and dependencies to the United Kingdom) resented this arrangement and worked against the new political establishment, albeit unsuccessfully in most cases.

In contrast, France's reluctance to let go of its colonies and willingness to use its military led to attempts to accommodate its colonies into new postwar relationships with metropolitan France. The French Union (1958–1960), which granted the African colonies greater political representation, failed when France proved unwilling to provide funds for economic and infrastructural development. Such limitations convinced post-colonial communist leaders that Europeans were merely interested in economic issues and not the interests of subject regional populations. In addition, armed revolutionaries in Indochina (1954) and Algeria (1962) managed, with Soviet support, to oust the French, severely discrediting the future of French imperialism and creating support for local communist (and nationalist) insurgents. Congolese resistance to colonial rule eventually led to the withdrawal of Belgian

forces and the subsequent development of an independent Democratic Republic of Congo in 1960. In the midst of the ensuing civil war in Congo and other conflicts, decolonization proceeded, sometimes quickened by the restlessness of communist (i.e., Malaysia, Vietnam) and communist-backed insurgencies (i.e., Kenya, Angola). Decolonization and the prevention of neocolonization were seen as the necessary preconditions of ensuring political self-determination on the road to socialism and augmented the ideological rhetoric espoused by insurgents, much of it already encouraging resistance against the exploitative and weakened European colonialists.

Communist insurgents and activists in post-colonial societies regarded Soviet support as necessary to oust the European colonizers (and the perceived U.S. neoimperialists). Encouraged by communist successes in North Korea (1950–1953) and Vietnam (1946–1954), communist leaders strongly advocated combating European-style occupational armies via guerrilla warfare in the countryside (i.e., Maoism). Armed guerrillas working in tandem with the peasantry became a vital factor in the struggle against either the colonial powers or the elites, perceived as capitalist puppets left in place after decolonization. Communist insurgent leaders such as North Vietnamese Ho Chi Minh and Cambodian Pol Pot took these lessons to heart, the former in his fight against both France (1954) and the United States (1964–1975) and the latter in his genocidal purges of urban elites during the Khmer Rouge (1975–1979). The Cuban Revolution of 1959, under Fidel Castro and the legendary and almost mythological Che Guevara, spearheaded the communist movement in Latin America, illustrating the widespread resentment against U.S. economic hegemony in the Western Hemisphere. Latin American revolutionaries sought to oust capitalist elites, whom they viewed as U.S. cronies. Drawing on Cuban support and indirect Soviet support, communist revolutionaries in such places as Bolivia, Nicaragua, and El Salvador worked against their existing political establishments through guerrilla warfare, peasant upheavals, and open warfare. U.S. involvement through CIA coups and the installation of pro-U.S. dictators (the overthrow of Salvador Allende in Chile in

➤ MAOISM

Maoism (Mao Zedong thought) is an interpretation of Marxist-Leninism derived from the teachings collected in the widely distributed *Little Red Book*, formally known as *Quotations of Chairman Mao Zedong*. It was widely disseminated throughout the population during the Cultural Revolution (1966–1976) in the People's Republic of China (PRC) as the official doctrine of the Chinese Communist Party (CCP) and emphasized the role of the peasantry in the coming revolution against capitalism. Since China lacked a substantial middle class (bourgeoisie) and the requisite working class (proletariat) necessary for an orthodox Marxist revolution, Mao foresaw the need to employ the demographically large Chinese peasantry to fulfill this task. Maoists attempted to mobilize and organize rank-and-file guerrilla fighters from the peasantry, creating rural sanctuaries in peasant communities while increasing coordination among the guerrillas and then transitioning to conventional warfare. Maoist military doctrine emphasizes the role of the peasantry in keeping the guerrilla fighters logistically supported and hidden.

Maoism and its emphasis on rural peasant participation in revolution had a significant influence throughout much of the developing world (i.e., Latin America, sub-Saharan Africa, and Southeast Asia) in the second half of the twentieth century. Maoist precepts were also embraced—with violent and absurd consequences—by the New Left throughout the West. Mao's admirers agreed that only through mobilizing the peasantry, much in the same way Mao conducted the Great Leap Forward or the Cultural Revolution, could revolutionary ends be achieved.

—Abraham O. Mendoza

1973 being the most notorious) did much to galvanize these movements.

As communist revolutionaries throughout the developing world saw many of their countries enter an uncertain period of development, many sought foreign assistance from the Soviet Union. Many African and Asian countries, even Non-Aligned Movement (NAM) countries such as Egypt, wished to develop their economies in a

way that would allow them to proceed on the path of building socialism and modernization. Soviet engineers, advisers, and funds poured into African, Asian, and Latin American countries (mainly Cuba) to assist in these endeavors. However, with Cold War military expenditures draining resources, Soviet aid was not substantial enough to help these countries be self-supporting. This led some of them to seek more financial assistance from the United States or Europe (primarily through the World Bank or the IMF, seen as neocolonial methods of economic control). In spite of these shortcomings, communist revolutionary movements in the developing world continued to look to the Soviet Union for military, diplomatic, and economic support (not to mention as a model) in the face of their economically dependent position vis-à-vis the West while continuing to utilize revolutionary warfare methods learned from World War II and the Chinese example.

Zionism, Post-1945

Zionism, a multifaceted Jewish national liberation movement, has undergone a series of redefinitions since its initial development in the late nineteenth century. While most written histories of the Zionist movement conclude with 1948—the year of the foundation of the State of Israel—Zionism remains a controversial mainstay of contemporary political discourse. Since attaining its preeminent goal of establishing a national Jewish homeland in Palestine, Zionism has been rooted in the assertion of Israel's right to exist and the Law of Return extending the right of citizenship to any Jew wishing to make *aliyah* (literally “going up,” or settling in Israel). The

term has also come to represent the political, financial, and spiritual support of the State of Israel by Jews living in the Diaspora.

By 1945, the Jewish population of the Yishuv (“settlement”) in British Mandatory Palestine numbered over 500,000. Growing Zionist demand for a Jewish homeland had been rebuffed by the immigration restrictions imposed by the White Paper of 1939 and further exacerbated by the continuous revelation of the realities of the Holocaust. By 1946, British authorities overlooked the flow of refugees into Israel that far exceeded the 75,000 allowed by the White Paper. Facing an exhausted military and economy after the war, Britain had grown weary of worrying about Palestine, and political maneuvers could not resolve the issue in a manner that would placate the Palestinian Arabs and satisfy the Zionist Jews. Thus, the issue of Palestine was forwarded to the newly established United Nations (UN), which reached the conclusion that partitioning Palestine was the only workable solution. In November 1947, the UN voted to partition Palestine into two separate states, one Arab and the other Jewish; following the adoption of the partition plan, a civil war erupted throughout Palestine.

On May 14, 1948, the British mandate for Palestine expired. David Ben-Gurion, Israel's first prime minister, utilized this moment to proclaim the Declaration of Independence of the State of Israel. Almost immediately, Egyptian, Syrian, Iraqi, and Lebanese soldiers invaded the new state, effectively transforming the Palestinian civil war into a full-fledged war between the State of Israel and surrounding Arab states. By January 1949, Jewish forces had defended the territories of the 1947 partition and captured a considerable amount of Arab land. The cease-fire lines established by the armistice agreements made in 1949 increased Israeli territory to up to 78 percent of the physical area of mandatory Palestine. However, the Arab-Israeli War of 1948 neither ignited nor ended the hostilities between Zionist Jews and nationalist Palestinian Arabs.

During Israel's formative years, Zionism's function was clearly political and practical; the momentum of the Zionist movement helped consolidate the government and strengthen na-

tional defense while at the same time mediating between the new state and world affairs. In effect, Zionism served as the foundational *raison d'être* for the State of Israel. A principal shift in the meaning of Zionism was facilitated by the concurrent shift in Israeli demographics brought about by territorial expansion and a massive influx of immigrants. The differences of opinion over the definition of Zionism arose primarily between Israeli politicians and American Zionists. After 1948, the World Zionist Organization (WZO) had continued its operations, focusing on fund-raising and facilitating immigration to Israel. Yet most of these Zionists had little desire to emigrate. They were content with remaining in the Diaspora, a reality anticipated by the spiritual Zionist Ahad HaAm (1856–1927). Following HaAm's vision, such Zionists wished to remain in the Diaspora while aiding in making Israel an exemplary cultural and spiritual center. Eventually, conflicting views concerning the would-be characteristics of a shared partnership between Israel and Zionist organizations in the Diaspora intensified the confusion over the definition of Zionism.

Ben-Gurion and other Israeli Zionists vehemently rejected the HaAmist version of spiritual Zionism. They envisioned a dissolution of Diasporic Jewish identity alongside Israel's development as the singular geographical location for Jewish civilization. This "negation of the Diaspora" (*Shelilat baGolah*) infuriated Zionist leaders such as Emanuel Neumann, president of the Zionist Organization of America, who opposed Ben-Gurion's emphatic definition of Zionism as eventual immigration to Israel. At the same time, rejecting the validity of Jewish identity in the Diaspora threatened the value of Western Zionist organizations, especially in terms of their political and financial support for Israel.

Eventually Israel and the WZO reached an official agreement stipulating that the responsibilities of the WZO would remain in the area of immigration assistance and fund-raising. Nevertheless, among the younger generation of Israeli Jews, the term "Zionism" came to be considered a pejorative synonym for "empty talking," reflecting the predominant association of Zionism with personal aliyah and subsequent disdain for

➤ JEWISH ANTI-ZIONISM

While Jewish organizations across the world primarily support Israel, some groups and individuals within the Diaspora and Israel continued to reject Zionism after the creation of the state in 1948. Such Jewish anti-Zionism involves a fundamental opposition to the founding of the Israeli state or to the story of that founding and tends to be either religious in nature or revisionist. Opposition to Zionism from Jewish religious groups stems primarily from *haredi* (Orthodox Judaism) sects, such as the Satmar Hasidim, Edah HaChareidis, and Neturei Karta. These *haredi* groups reject the sovereignty of a Jewish state in the land of Israel because the War of Independence preempted the messianic era foretold by the biblical prophets. The establishment of the State of Israel is interpreted as an act of impatience, violating the biblical demand to wait for the Jewish Messiah. An extreme faction within Neturei Karta caused considerable controversy when, in December 2006, some of its members attended the International Conference to Review the Global Vision of the Holocaust convened in Tehran by the president of Iran, Mahmoud Ahmadinejad. They were not Holocaust deniers but objected to the invocation of the Holocaust to legitimize the founding of the Israeli state. Another source of anti-Zionism sentiment emerged in Israel in the form of revisionist history. In the 1980s, a group of Israeli historians utilized access to declassified Israeli documents to reevaluate the plight of indigenous Palestinians throughout the 1940s. These so-called New Historians, such as Benny Morris and Ilan Pappé, question the traditional Zionist narrative, a story dominated by struggle, sacrifice, and heroism culminating in the triumphant return to the land of Israel. Their acknowledgment of the Palestinian exodus of 1948, or Nakba (Disaster), for example, was one of the foundational steps in rewriting Israeli history to include, for the first time, the victimhood of the Palestinians. This academic turn toward questioning Zionist ideology contributed to the so-called post-Zionist attitude present in contemporary Israeli society.

—Blake W. Remington

those who remained in the Diaspora yet considered themselves Zionists.

The Six-Day War of June 1967 served as a watershed moment for Israel and Zionism alike. Israel's success in capturing the remaining territory of pre-1948 Palestine—including the West Bank and the Gaza Strip—resulted in an outpouring of support from Diaspora Jews and an intensification of anti-Zionist sentiment among Arab states, which had repeatedly rejected Zionist claims. The dispute over Israel's borders led to the Yom Kippur War only six years later. Arab allegations of Israeli imperialism also contributed to a 1975 UN Resolution equating Zionism with racism. However, in 1991, the UN General Assembly repealed the resolution by an overwhelming vote.

Despite the fact that the Jerusalem Program—adopted at the World Zionist Congress in 1951 and revised in 1968 and again in 2004—stipulated the ingathering of the Jewish people in Israel via worldwide aliyah as a main component of Zionism, Zionist organizations continued to operate in the Diaspora. In America and other Western democracies, Zionism took the form of cultural and religious education, with a dual purpose of stimulating support among Jewish communities and increasing global acknowledgment of Israel's rightful existence. In the 1970s and 1980s, Zionist organizations focused their efforts on the plight of Jews in the Soviet Union who, following the collapse of communism, were finally able to emigrate to the West.

Current debates within Israel question whether Zionism has been rendered obsolete by the movement's own political and cultural accomplishments: Israel exists as an independent state and houses half the world Jewish population, and Hebrew has been revitalized and transformed into a national language of both business and literature.

Anti-Zionism

The concept of anti-Zionism encapsulates the attitudes of individuals or organizations opposed to the formation or existence of the State of Israel or its expansion into the Palestinian occupied territories. Anti-Zionism is a controversial theme in the contemporary world since it is inclusive of a variety of groups ranging from neofascist anti-Semites in right-wing fringe parties throughout the West to Islamic fundamentalists, Arab nationalists, Marxists, socialists, and people critical of Israeli policies in the Palestinian territories. In defining anti-Zionists, one must distinguish between anti-Semites bent on the destruction of the State of Israel and its inhabitants, those critical of Israel's existence in the Middle East, and those who are critical of Israeli policy in the Occupied Territories.

In the immediate aftermath of World War II and the liberation of the Nazi death camps, Jewish emigration from Eastern Europe surged toward British Mandatory Palestine. This followed a half-century of gradual Jewish immigration to the region from Eastern Europe under the auspices of various Zionist organizations. After 1945 increased immigration fueled tensions between Jewish settlers and indigenous Arab residents. The formation of the State of Israel in 1948, recognized by the United Nations, further aggravated the issue, leading to open war between Palestinian Jews and Arabs.

Anti-Zionism emerged within the Communist Party of the Soviet Union in a policy of resistance to the formation of the State of Israel or any sympathy toward a Jewish identity associated with such a state and in efforts to persecute prominent Jewish leaders within the party and the state. While the Soviet Union ultimately supported the formation of the State of Israel in 1948, traditional Russian anti-Semitism lingered in the top ranks of the Soviet leadership. The Soviet leadership itself contained a number of assimilated Jews who did not adhere to Zionism and believed that the draw to emigrate was just another nationalist bourgeois ploy that would

hinder the advance of socialism among Soviet Jews. Nonetheless, under the pretext of harboring Zionist sympathies, Soviet Jews experienced a high degree of scrutiny and suspicion under the Soviet state. In 1952 Josef Stalin plotted directly against Jews in the Soviet Union, deciding to purge Zionists and so-called cosmopolitans (Jewish intellectuals) from Soviet society. Using the pretext of a doctors' plot to poison Stalin, Soviet authorities rounded up Jewish doctors and accused them of Zionism and of working with the United States as Jewish bourgeois-nationalists. However, Stalin's death on March 5, 1953, prevented the Jewish doctors from being put to death or prosecuted any further. Nonetheless, Soviet suspicions of Zionism of Soviet Jews and Jews in general continued throughout their reign within the Soviet Union and in much of the Eastern Bloc.

The mere existence of Israel in the Middle East, surrounded by Arab and Muslim neighbors hostile to what was seen as an infringement into the land of Islam, has led to the emergence of strong anti-Zionist attitudes among Arab nationalists and Islamic fundamentalists throughout the region. The wars of 1948, 1956, 1967, and 1973, resulting in losses of territory and lives on the part of the Arab states, created long-term resistance against the State of Israel. The issue of the Palestinian Occupied Territories and the plight of its peoples as well as the plight of Palestinian refugees in adjacent countries further exacerbated the situation. Arab nationalists, such as Egyptian president Gamal Abdel Nasser and the Baath parties in Syria and Iraq, viewed Israel as a Western enclave, a constant reminder of previous centuries of European colonization of the region. In contrast, Islamic fundamentalists, particularly after the war of 1967, viewed Israel as an affront to the unity of the lands of Islam, particularly with the occupation of the city of Jerusalem in 1967 and the alleged Israeli oppression of their fellow Muslim Palestinians.

The terrorist organizations Hamas, Hizbullah, and Islamic Jihad developed in the late twentieth century and openly advocated the destruction of the State of Israel. Such organizations emerged from widespread Arab and Muslim disdain of the Jewish state. Both Arab nationalists and Islamic fundamentalists have developed anti-Semitic rhet-

➤ MODERN ANTI-SEMITISM

In contrast with previous historical modes of anti-Semitism, modern anti-Semitism is heavily influenced by the global anti-Zionism shaped by the Arab-Israeli conflict in the Middle East centered on the Palestinian-occupied territories. Modern anti-Semites are openly critical of U.S. support of Israel and the role of the Israel lobby in securing this support, claiming that this political clout is evidence for Jewish control of the U.S. government akin to the type of conspiracy theories espoused by National Socialists in 1930s' Germany. Such alleged Jewish control of government is depicted in the right-wing extremist novel *The Turner Diaries* by Andrew MacDonald, offering a story about the "Zionist Occupation Government" (ZOG) and its policies of multiculturalism and seizure of guns. The book describes an ensuing widespread race war in the United States that ends with the extermination of Jews and non-whites at the hands of the "Organization," which promotes white supremacy. Another conspiracy theory places the blame for the September 11 attacks on Jews, alleging a Jewish conspiracy to provoke an American reaction against Islam to the benefit of Israel. Much of this anti-Semitic discourse is available on the Internet and is referenced by Western neofascists, Islamic fundamentalists, and left-wing fringe extremists alike, illustrating the complexity of modern anti-Semitism in invoking older anti-Jewish myths and combining them with modern global anti-Zionist attitudes.

—Abraham O. Mendoza

oric in their anti-Zionist policies, indoctrinating and advocating racism and visceral hatred of Israelis, the State of Israel, and Diaspora Jews throughout the world.

Right-wing fringe parties and organizations in Western Europe and the United States, such as neofascists, neo-Nazis, and racist factions, also have openly advocated anti-Zionism as a way to legitimize their anti-Semitic and racist agendas by using the rhetoric of criticism of the State of Israel and its policies. Political parties such as the Front National in France, the British National Front in the United Kingdom, the American Nazi Party in the United States, and the National Democratic Party of Germany are openly critical of

Palestinian supporters of the militant Hamas group, which advocates the dissolution of the State of Israel, celebrate the Israeli pullout from Gaza on September 11, 2005, in the West Bank city of Birzeit. (Abbas Momani/AFP/Getty Images)

the State of Israel and its policies. These parties also recirculate older anti-Semitic myths of global Jewish conspiracies to take over the world through the control of Western governments, the media, and international finance. Relying on anti-Semitic texts such as *Mein Kampf* and *The Protocols of the Elders of Zion*, many of these parties and organizations have managed to transmit these older ideas into their anti-Zionist agendas and Holocaust denial allegations.

The political Left throughout Europe, the United States, Latin America, Australia, Africa, and Asia have also developed anti-Zionist positions, particularly after the 1967 war. However, their form of anti-Zionism is less tinged by anti-Semitic discourse and more focused on the plight of the Palestinian Arabs in the Occupied Territories. Following the 1967 war, Israel changed in the eyes of the world from a tiny state surrounded by hostile neighbors to one openly engaged in colonizing its weaker neighbors. This drastically altered the attitudes held toward Israel by the political Left throughout the world.

Once seen as a model of socialism, with its kibbutzim and secular political system, it became yet another example of colonial oppression in the contemporary world. Third World revolutionaries, Maoists, New Left movements, and socialist parties throughout the world became vocal in their criticism of Israeli policies and their continuing occupation of the West Bank and Gaza and gave moral weight to the Palestinian cause. While there are some instances of anti-Semitism in the remarks of some factions within the global political Left, much of its message focuses on Israeli policies against the Palestinians and criticism of U.S. support for Israel.

Public Memory of Postdictatorial Societies

In the twentieth century, numerous dictatorial regimes emerged and dissolved. The nature of the transition from dictatorship to democracy determined the ways in which postdictatorial societies dealt with past crimes against humanity. In Spain, Uruguay, and Chile, for instance, indictments of individuals responsible for human rights abuses were prevented by amnesty laws enacted by the former rulers. The main argument for such laws, which had been imposed by former dictators but were upheld by democratically legitimized legislations and plebiscites, was that a reckoning with past crimes would divide society and prevent national reconciliation. Therefore, many postdictatorial governments, as in the case of Spain in regard to the Francisco Franco dictatorship, embarked on a policy of national amnesia.

José Zalaquett, a member of the Chilean Truth and Reconciliation Commission, provided a typology of situations for the transition from

repressive systems to democratic rule and the consequences for dealing with crimes and abuses of the past system. His first category refers to a situation of clear victory over the previous dictatorship, such as in the case of the Allied victory over Nazi Germany (1945) and the Sandinistas' successful struggle against the former dictator Anastasio Somoza Debayle (1979). Such a situation gives the victor unlimited power to impose punishment for past crimes (Nuremberg War Crimes Trials). The second category describes situations, as they occurred in Greece (1974) and Argentina (1983), in which the military rulers relinquished power as a result of an embarrassing military defeat. Since the military found itself in a weak position, it could not impose its conditions. As a result, civilian governments were able to revoke amnesties and to put high-ranking officers on trial for human rights abuses. However, while human rights violations in Argentina were significantly greater than in Greece under military rule, the postdictatorial government of Greece succeeded in convicting many more military personnel than the Argentinean government. By 1976, between 100 and 400 trials for torture were held throughout Greece, and the top-ranking officials of the military junta were put on trial. In contrast, in Argentina only 16 officers were indicted and 10 convicted of human rights violations. The third category is based on the experience of Chile (but also applies to Uruguay and Spain), where the dictator and the military relinquished power at a moment of strength. The military allowed for a democratic transition and, in return, imposed its conditions on the process. Since Chilean society was deeply divided over the evaluation of Augusto Pinochet's rule, the military still plays a significant role in the postdictatorial state. The fourth category refers to a gradual transition from dictatorship to democracy such as that which occurred in Brazil, where postdictatorial governments emphasize the prevention of future human rights abuses rather than an investigation of past crimes.

In the case of Spain the policy of forgetting the past also included the decision to seal the police files from the Franco era indefinitely. Such a decision characterized the dealing with dictatorial pasts in many countries. Only in the case of South Africa because of its truth commission

➤ VALLEY OF THE FALLEN

Typically, modern dictatorships have, more often than not, caused physical and psychological damage to the populations over which they have held control. Furthermore, they left behind monuments dedicated to their leaders. These monuments often attracted the outrage of people in popular revolutions, and their removal was part of the symbolic liberation from dictatorial dominance. The end of communism in Eastern Europe was therefore closely related to the removal of Lenin statues from public spaces. In the case of Spain, however, one of the most horrific monuments to dictatorial power still attracts hundreds of thousands of tourists each year. The Valley of the Fallen was built in the years from 1940 to 1959 through the forced labor of political prisoners and opponents incarcerated in concentration camps. It consists of a Catholic Church (the largest in the world) built into a mountain with a gigantic cross (the largest freestanding cross in the world) on its summit. This church still contains the sarcophagi of Generalissimo Francisco Franco and of former dictator José Antonio Primo de Rivera, the founder of Spain's fascist movement Falange Española. Moreover, to this very day it attracts right-wing organizations, which commemorate Franco's and Primo de Rivera's deaths on November 20th on a yearly basis.

—Thomas Adam

and in the case of the German Democratic Republic (GDR) were crimes and those who committed them under the mantle of the previous dictatorial regimes disclosed to the public. The GDR is an exceptional case in that the archives of the former state secret service were opened to the public. After unification with the Federal Republic of Germany (1990), the German parliament established in 1991 an agency with the task of making the files produced by the East German Stasi (secret service) available to those individuals who had been spied upon by the Stasi. In effect each East German citizen thus gained the right to see the information collected about him or her by the state security. In addition, the German parliament passed a law banning the employment of individuals as civil servants and

in public office who had formerly collaborated with the Stasi. In the case of the East German state of Saxony, the state legislature even included in the state's constitution an article (Article 118) that allows parliament to expel an elected member of parliament if he or she had collaborated with the Stasi.

Such lustration laws are characteristic for some but not all former communist countries. In the case of Czechoslovakia, a law from 1991 prohibited high-ranking functionaries of the former Communist Party, members of the State Security Agency, and the People's Militia as well as collaborators from holding senior administrative positions in government, the military, the police, the intelligence service, state-owned media, and state-owned enterprises for five years. Poland attempted to follow East Germany's lead several times and enacted lustration laws in 1992, 1998, and 2007. However, Poland's constitutional court declared each of these laws unconstitutional and thus prevented the investigation of collaborators with the secret service during the communist dictatorship.

Lustration laws as a means of dealing with a dictatorial past have remained an East European phenomenon for a number of reasons. Dictatorships in Africa, Asia, and South America have not assembled such detailed records of collaboration between individuals and the regimes. And even if such records existed, they have been destroyed in the course of transition. Furthermore, political transitions especially in Africa and South America were often the result of negotiations that included agreements on the protection of those who had supported the former regime in one way or another. In their efforts to resolve the past, postdictatorial societies in Africa and South America chose to employ truth and reconciliation commissions, created immediately after the political transition toward democracy. Priscilla B. Hayner counted at least 21 truth and reconciliation commissions created since 1974. However, the scope of inquiry and the authority of these truth commissions differ widely. The South African Truth and Reconciliation Commission (TRC) created in 1995 was the first such commission created by an act of parliament. Its task was to uncover the crimes against humanity under the system of apartheid (1960–1994) in

order to facilitate national unity and reconciliation. For this purpose, the TRC was charged with producing as complete a picture of the past as possible by collecting statements from victims and perpetrators of past crimes. To secure the participation of perpetrators, the TRC had the power to grant amnesty to persons who fully disclosed their participation in those human rights abuses. In contrast, truth commissions in Argentina, Chile, El Salvador, and Guatemala did not possess such far-reaching powers. These commissions were not endowed with any subpoena powers and were not in a position to grant amnesty for testimony. They completely relied on the voluntary cooperation of individuals and their willingness to testify publicly, leaving an incomplete picture.

Conspiracy Theories in the United States

Although conspiracy theories have been a part of American history at least as far back as the founding of the nation, the astounding and frightening use of new technologies during World War II, together with anxieties about amorphous, duplicitous enemies, gave rise to a whole host of creative and long-standing mythologies about government cover-ups and alien intrigue. From the Cold War to the modern era, these theories have fed on the fact that in the name of national security, the U.S. government regularly classifies and withholds information from the public. Ultimately, conspiracy theories may be a way for people worldwide to make sense of the threats, dangers, and complexities they see in the modern world.

After World War II, those who reflected on the destruction wrought on Hiroshima and Nagasaki realized that America now possessed the capacity to annihilate entire cities. Some tried to put a positive spin on atomic energy; many popular American magazines and advertisements celebrated the term “atomic,” with one article even suggesting that atomic medicine would enable paraplegics to walk again. Yet once the Soviet Union developed its own atomic and hydrogen bombs, the terrifying specter of nuclear war produced a slew of conspiracy theories by people trying to make sense of the ensuing nuclear arms race.

The combination of this frightening new technology and the secrecy surrounding its development encouraged modern conspiracy theories about a supposed U.S. government cover-up of aliens and UFOs. The secret facility where the atomic bomb was developed was in Los Alamos, New Mexico, and after World War II the government continued to perform secret experiments in Roswell, New Mexico. The secrecy surrounding such projects led to wild speculation about their nature and intent and fostered the conspiracy theory, still active today, that the U.S. government had found evidence of alien life in Roswell but was hiding the fact from the American public and the world.

The sheer brutality of World War II, epitomized by the horror of the concentration camps in Nazi Germany, gave credence to postwar fears that undemocratic countries were bent on destroying democracies and that they would stop at nothing to do so. The subsequent fears of atomic warfare led to theories about the underhanded tactics that communists would use to subvert democratic nations. In America these conspiracies were exploited in the 1950s by politicians such as Wisconsin senator Joseph McCarthy, who inflamed growing paranoia of communist takeovers by brandishing lists that contained, he said, the names of communists employed at the highest levels of government. Anticommunists used the House Un-American Activities Committee (HUAC) to badger and intimidate witnesses into admitting their past involvement with supposedly subversive organizations and activities. Although fear of communist espionage predated McCarthy and anticommunism—indeed, the Sen-

➤ THE X-FILES

A huge hit in the 1990s, *The X-Files* was a U.S. television series that followed the adventures of FBI special agents Fox Mulder and Dana Scully as they pursued a multitude of conspiracy-tainted mysteries. The show’s mottos, “I Want to Believe,” “The Truth Is Out There,” and “Trust No One,” all spoke to the strong appeal of conspiracy theory culture. The show’s writers hinted that the government and even the FBI itself was behind many of the paranormal mysteries and that government officials had hidden, invented, or developed alien organisms. The series never clearly revealed whether the government was faking the existence of aliens or aliens were insinuating themselves into the government. Much like real conspiracy conspiracists, fans of *The X-Files* could speculate endlessly on their beliefs about the series and yet never actually confirm those theories beyond the shadow of a doubt.

—Joel Silverman

ate formed HUAC back in 1938—McCarthy, his fellow anticommunists, and FBI director J. Edgar Hoover endorsed the idea of a communist conspiracy.

In America, fears stemming from government secrecy merged with anxieties about foreign communist intrigue in 1963 after President John F. Kennedy was assassinated. More than 2,000 books have been published about the assassination, and while the theories surrounding the assassination differ, more than four decades later the conspiracy theories linger. Many of these theories stem from the argument that Lee Harvey Oswald, who was arrested for the assassination, was not and could not have been the lone gunman. One theory that many conspiracy theorists embrace is that the CIA, supposedly frustrated with Kennedy’s weak stance on communism and threatened by his disapproval of the agency, planned his assassination. Another posits that FBI chief J. Edgar Hoover, similarly threatened by Kennedy’s policies, arranged the murder. Yet another theory insists that Kennedy’s vice president, Lyndon B. Johnson, had his boss killed in Johnson’s home state of Texas so that

he could take over the presidency. Whether conspiracy theorists point to the Mafia, anti-Castro Cuban exiles, or Union Teamsters, the one common thread to these wildly disparate theories is the assumption that the U.S. government covered up the truth of the Kennedy assassination. Similar conspiracy theories surround the 1968 assassinations of Martin Luther King and Robert Kennedy.

Although no credible evidence has come to light to support any of these theories, the exposure of actual government cover-ups, such as those of the Watergate Scandal and of American covert military operations, has buoyed conspiracists. While some contemporaries dismissed the original crime that led to the Watergate Scandal as a third-rate burglary, the facts that emerged from the investigation into the men who orchestrated the break-in to the Democratic National Headquarters in 1973 illustrated that highly placed government officials were willing to break the law with impunity and that politicians, and even presidents, might use lies and deceit to cover up those crimes. To those who believed in conspiracy theories, the downfall of Richard Nixon and the imprisonment of some of his staff did not demonstrate that governments were unable to maintain secrecy forever. Rather, for conspiracy theory buffs, the disclosure of such foul play simply served as evidence that the U.S. government could not be trusted.

Although conspiracy theorists might belong to fringe groups, the fascination surrounding aliens, foreign intrigue, and government cover-ups has resulted in a wealth of movies, television shows, Web sites, and other popularizations of conspiracies. Hollywood aided the cause early in the Cold War, producing numerous films

depicting insidious communist spies and fellow travelers. But after the Cold War ended and the threat of communism seemingly vanished, Hollywood and television producers continued to revel in the drama of the conspiracy theory, most notably with the movies *J.F.K.* (1991) and *Conspiracy Theory* (1997) and the hit television show *The X-Files* (1993–2002).

As the Internet gained in popularity, conspiracy theory sites about aliens, the Kennedy assassination, and countless other plots have sprouted up. The mainstream media frequently documents these theories online, thereby disseminating them to a larger readership. Major news organizations reported, for example, on a 2005 study showing that almost 50 percent of African Americans believe that the government engineered and then spread the AIDS virus. Most recently, conspiracy theories abound about the U.S. government's role in the terrorist attacks of September 11, 2001; about the government's response to Hurricane Katrina in 2005; and about the Bush administration's true motives in the Iraq War.

■ Introduction: Theology and Thought

The Cold War dynamic encouraged rather simple nationalistic messages that included anticommunism and procapitalism in the West and its opposite in the communist world; nevertheless, authority was in crisis. A general

skepticism with authority marks much of popular, academic, and even religious thought for the post-1945 period. The Holocaust, the atomic bombing of Japanese cities, the atmosphere of reprisals and devastation that followed World

War II, and the ensuing nuclear arms race proved troubling in the extreme to people of conscience. The authority of mainstream religion was on the wane. In 1966, *Time* magazine ran the cover story "Is God Dead?" that highlighted the thought of Christian theologians, public intellectuals, and everyday people in their efforts to redefine "God" or to imagine a religion without one, often by looking to existentialism. Existentialism offered a modern variant of stoicism, with its demand for moral duty to one's self in an absurd universe. Existentialism also remained popular in mainstream discourse in the 1950s in such venues as crime novels and crime films, and in magazine profiles of jazz musicians and beat generation literary celebrities.

Established religion was not the only faith under attack. Films that featured mad scientists concocting blobs that escaped laboratories or Godzilla rearing his head from atomic seas not-so-subtly critiqued an overreaching faith in science and technology. The absurd, often infantile, yet imaginative advertising pitches that saturated the media in the West deepened a tradition as old as P. T. Barnum that encouraged in the public a healthy skepticism of the advertising that sustained consumer economies. The civil rights movement and the antiwar movement in the United States, anticolonial movements in the developing world, the Solidarity movement in Poland, and the underground networks in the Soviet Union that disseminated forbidden samizdat literature critical of the Soviet Union also showed that political authority could be challenged.

In the academic world and associated media, an at times not very rigorous relativism flourished, spreading from literary criticism and philosophy to popular culture. New liberation movements that included Marxism, feminism, gay rights, and animal rights encouraged the exposure of hidden assumptions that recapitulated the status quo power arrangement; according to this method of inquiry, linguistic analysis shed light on the power hierarchy that underpinned political life, gender relations, race relations, and beliefs related to sexuality or nature. Paradoxically, the authority of skepticism was also challenged. A conservative reaction to demands for tolerance and the purported moral malaise

inevitable in endless relativism were nurtured throughout this period.

Fundamentalist religious thought returned with renewed vigor in Islam, Judaism, Hinduism, and Christianity in a rejection of what was seen as moral decline. Often fundamentalist theology was sharply linked to a political agenda and the goal of reinstilling morality. At the same time, secular conservatives attacked politically correct thought as a form of censorship. Globalization, the growth of diaspora communities, and the challenges of multiethnic populations (for example, the 2004 beheading of the Dutch filmmaker Theo van Gogh, who had made a film about spousal abuse of an Islamic woman) also led to public debates over the value of cultural relativism and the demands for inclusion that had previously been unquestioned.

The dialectic between tradition with its promise of order and innovation with its accompanying demand for tolerance continues unresolved.

—Fred Nadis

Developments in Philosophy since 1945

Philosophy in the second half of the twentieth century continues to develop from noticeable presuppositions that have molded philosophy since the eighteenth-century philosopher Immanuel Kant. This includes the continued division within Western philosophy between analytic philosophers and continental philosophers. While analytic philosophers have focused on the logical structure of language and meaning in relation to use, continental philosophers have furthered the Kantian distinction between being-in-itself (noumena) and being-as-experienced (phenomena) and have pursued questions about the meaning of existence. Recent developments also include the rise of postmodernism, which has influence in both analytic and continental philosophy. Yet all three of these schools share common ground, including the rejection of metaphysics and its attempts to make definitive analyses of reality and shift to a focus on language and the move from skepticism about values (related to skepticism about metaphysics) to relativism and nihilism about values. All of these trends

indicate larger concerns about the relationship between philosophy answering foundational questions (or failing to do so) and the rise or collapse of civilizations.

The most formative philosopher of the twentieth century is commonly believed to have been Ludwig Wittgenstein (1889–1951). The early Wittgenstein (based on his first book, *Tractatus Logico-Philosophicus*) was influential before 1945 and continued to have influence after that, but the latter Wittgenstein (based on his book *Philosophical Investigations*) is particularly prominent after 1945 (it was published in 1953). The latter Wittgenstein rejected his earlier search for the perfect language and instead focused on language in its use. This involved what he called language games and the family resemblance between words (as opposed to direct or ideal reference whereby meaning is determined by the reference of a word to an object or idea).

The analytic philosophers incorporated the latter Wittgenstein into linguistic analysis. Instead of reducing ordinary language to a perfect logical language as in earlier efforts, they instead analyzed language in terms of use and pragmatics. This continued the theme of skepticism in that ordinary use and pragmatism do not admit certainty or metaphysical truths.

Phenomenology and existentialism, both offshoots of continental philosophy, trace their influence to Edmund Husserl (1859–1938). Through Husserl, Martin Heidegger (1889–1976), and Jean Paul Sartre (1905–1980), this branch of philosophy was more humanistic in its orientation than was analytic philosophy. It was humanistic in the sense of asking questions about what it means to be a human, how to lead a meaningful life, and what actions are free and genuine. Wittgensteinian influence can also be seen here in the later Wittgenstein claim that meaning must be understood in terms of language games and their use by humans. Meaning is given by humans rather than being discovered by humans.

There was also a revival of the philosophy of religion. Especially traced to thinkers such as Alvin Plantinga (1932–) of the United States, this revival tended to focus on the acceptability of religious belief as opposed to a defense of the truth of religious belief. Rather than trying to demonstrate the truth of a religious claim, such

as belief in God, Plantinga argued for the warrant of this belief, or that the believer was not violating any epistemic duties in holding such a belief. Belief in God, according to Plantinga, is as warranted as belief in other minds, which is a belief that is generally accepted to be warranted. In contrast to the claim, made for instance by Marx and Freud, that religious belief is intellectually subpar, Plantinga maintained that religious belief is as warranted as materialistic belief.

This focus on warrant is part of a larger abandonment of the Enlightenment project of establishing truth and certainty. Thinkers such as Descartes had sought a secure starting point for philosophy and then built their philosophical system on that certainty. The second half of the twentieth century saw an emphasis on the inability to find such certainty. All starting points were thought to be relative to a given language. For example, the revival of the philosophy of religion, and especially Reformed Epistemology (represented by Plantinga), argued for the warrant of religious belief within a given language. While within one language game it might be true that God exists, this same claim is not necessarily true in all language games. This is a shift from thinking about reality to the way that humans represent reality. As such, it is a continuation of Kant's categories that distinguish between phenomena and noumena.

Postmodernism, which emerged in force in the 1960s, is an overarching title that applies to both analytic and phenomenological/existential philosophy. The emphasis in postmodernism is hermeneutical skepticism as opposed to the search for the universals and certainty that marked modernity. Hermeneutical skepticism can be seen in the analytic tradition's emphasis on language and in the continental tradition's emphasis on subjectivism and situatedness. This is a continuation of the latter Wittgenstein's emphasis on language games.

Postmodernism views the fundamental human relationship as power. This position is influenced by thinkers such as Michel Foucault (1926–1984). Language is used to justify power structures and to marginalize opposition. In deconstructing language, this use is exposed and undermined. However, this means that any attempt to justify a position is a power struggle

that seeks both to place one group in power and to marginalize other groups. According to this political analysis, the marginalized should express their position and seek to deconstruct hegemonies.

Philosophy after 1945 continues to struggle with the same questions that have been the subject of philosophy since its beginning. The split between the analytic and continental philosophers are similar to those present between the Greek materialists and Sophists. These patterns reflect an ongoing failure to establish an ultimate foundation from which to answer the basic questions raised by philosophy (questions about authority and knowledge, reality and the eternal, and value and the good). As both analytic and continental philosophers presuppose a form of skepticism about basic questions, they repeat the lessons of earlier philosophers. As the twenty-first century begins and brings old conflicts into new light, these basic questions remain to be answered in a way that will provide a foundation for knowledge.

Existentialism

Existentialism is a philosophical construct and corpus of ethical thought developed in the nineteenth century and expanded upon in the twentieth century. Existentialism explores both the solitude and uniqueness of the human condition within a universe that is unconcerned—or even antagonistic—toward humankind. Existentialism holds that the reason and purpose for human life are unknowable and thus that free will and personal responsibility govern the consequences of one's actions. In its broadest application, existentialism has been embraced in some form by twentieth-century theologians (Karl Barth and Reinhold Niebuhr), psychologists (Viktor Frankl

and Rollo May), writers (Albert Camus and Franz Kafka), and philosophers (Simone de Beauvoir, Martin Heidegger, and Jean-Paul Sartre). Existentialism has its roots in the thinking and writings of such nineteenth-century luminaries as Friedrich Nietzsche, Fyodor Dostoyevsky, and Søren Kierkegaard, among others.

Existentialism, like its immediate philosophical predecessors, is a sharp departure from traditional Western thought that holds that rationality and consciousness are paramount to understanding the human condition. According to Sartre, “existence precedes and rules essence.” Otherwise stated, there is no preexisting, predefined nature to humanity other than what the individual creates for himself. And because existentialism does not acknowledge God or a supreme all-knowing entity, human beings are free to make their own choices and will be judged exclusively by the actions and choices they take.

While a part of earlier intellectual currents and popular culture, existentialism became a powerful force in the aftermath of World War II. It is not difficult to understand how a reaction to that war followed by the onset of a Cold War that brought with it the constant threat of instantaneous nuclear annihilation might have given impetus to existentialist thinking. The isolation of each individual in an absurd universe and the humanistic yet stoic philosophy of existentialists seemed suddenly reasonable. The idea of random absurdity that existentialists see as part and parcel of the human condition became the subject of many influential plays and films. Some of the more influential playwrights who explored the theater of the absurd included Eugene Ionesco, Boris Vian, Samuel Beckett, Luigi Pirandello, and Edward Albee.

Translations of Sartre and Camus, particularly the latter's novel *The Stranger* and his essay *The Myth of Sisyphus*, fueled a fascination with existentialism in the United States in the Cold War era. Also influential at this time were the so-called Beat writers such as Jack Kerouac, Allen Ginsberg, and Lawrence Ferlinghetti who borrowed heavily from existentialist thought. On a more popular level, an existential style emerged as early as the 1930s in crime fiction and in film noir with their criminal or semicriminal anti-heroes operating in an amoral, indifferent world.

Those genres continued to thrive in the literature and film of the 1950s. An existential stance also inflected the highbrow films of Sweden's Ingmar Bergman, Italy's Michelangelo Antonio, and the New Wave cinema of France developing around the *Cahiers du Cinema* and new directors such as Jean Luc Godard with his 1960 debut film *A Bout de Souffle* (*Breathless*).

Other arts were influenced as well. The dominant post-World War II movement in painting of abstract expressionism placed primacy on the individual and spontaneity, with Jackson Pollock its most celebrated figure. Likewise, post-World War II developments in jazz, noticeably bebop, led by Charlie Parker and Dizzy Gillespie, celebrated the individual and an embrace of freedom and spontaneous expression. Theologians such as Martin Buber and Paul Tillich also grappled with existentialism in the interwar and Cold War years. One of the most famous products of Cold War concern with a silent universe emerged in the mid-1960s when popular magazines in the United States announced to the public that young Protestant scholars and theologians had begun the theological movement "God is Dead."

Epistemology

Epistemology, or the philosophical investigation of the basis of knowledge, has been characterized by skepticism since 1945. This is true of the continental and postmodern schools as well as in the analytic school (prevalent in academia in the United States and Britain). The condition of skepticism prevents foundational questions about what exists and what is good from being answered and built upon. This is especially problematic for epistemology, which has as its subject the idea of knowledge itself.

Hermeneutical skepticism, found in post-modern thinkers such as Michel Foucault (1926–1984) and Jacques Derrida (1930–2004), focuses on the nature of interpretation and the elements affecting interpretation. This approach, ultimately, is similar to the cultural relativism advanced by others in the history of philosophy, such as the Sophists of ancient Greece. This position justifies skepticism by noting, first, the failure of previous programs to achieve knowledge (in this case the Enlightenment); second, the reality of cultural diversity (brought to the forefront by globalization); third, the role of language in shaping what is discussed and how it is discussed; and finally, the relationship between power and knowledge on the one hand and, on the other, the vested interest of those in power to manipulate what is accepted as knowledge.

This hermeneutical skepticism leads to relativism, which in turn leads to nihilism. If meaning is relative to individuals or groups, then the world itself is not meaningful, but instead meaning is imputed by humans. The implication is that anything can be said to be meaningful, while nothing is actually meaningful. This raises significant existential problems about the meaning of life and the purposefulness of activity at the individual and group level. It also has devastating implications for philosophy and academia, since workers in these fields can no longer claim to have and teach knowledge.

In the analytic school a different path leads to the same skeptical implications. The focus of this philosophical tradition in the twentieth century has been on language. This began with the goal of finding the perfect language based solely on logic, a program attempted by Bertrand Russell (1872–1970) and Alfred North Whitehead (1861–1947) in their *Principia Mathematica*. As the century continued, this project was largely abandoned and replaced with an emphasis on the common usage of language. The reality of different languages also indicates the reality of different logical systems. If logic is conceived of as rules of inference, the initial rules that govern inferences are believed to be changeable and relative.

This claim led to a general abandonment of foundationalism. Common since the Enlightenment, foundationalism asserts that knowledge

claims are either self-evident truths or deduced from such. If there are no self-evident starting points, however, or if different logical systems have different starting points, then the foundationalist program cannot provide certainty. This raises questions about the nature of justification. Because of the problems surrounding justification, some philosophers began to emphasize alternative definitions of knowledge, such as warranted belief.

The Gettier Problem, found in the 1963 article "Is Justified True Belief Knowledge?" raises questions about the definition of knowledge. Up until this point it was assumed that knowledge, as stated in a specific proposition, is justified true belief. This means that persons have knowledge when they can state their belief in a proposition, their belief is true, and they can show that it is true. Gettier called this into question by giving examples where persons had justified true belief that did not appear to be knowledge. The examples he used involved persons who believed that something would happen and had justification for this belief, yet the event happened in a way that differed from the person's expectations. One philosopher offered a Gettier situation in which an observer believes that he or she has seen a sheep in a field, generating the belief or statement: *a sheep is in the field*. What the person was actually looking at, however, was a dog disguised as a sheep. However, another sheep was hidden behind a hill on the field. While the proposition technically fulfilled the criterion of a true statement, the person's justification was slender and skewed. So, although the proposition was true, it did not represent knowledge.

Many philosophers believe that the Gettier Problem demonstrates that an additional element must be added to justified true belief in order to arrive at knowledge. Others denied that the Gettier cases were instances of justified true belief. Another response is to distinguish between weak and strong justification, whereby weak justification is commonly accepted in human activities but does not provide certainty and strong justification, although less common, does provide certainty. While the Gettier Problem focuses on beliefs about matters of fact known through sense data, it does not address the issue of hav-

ing strong justification about the basic questions asked by philosophy; these include the nature of reality, what is eternal, and what is good.

The debate over the definition of knowledge is sometimes framed as a debate between externalists and internalists. The internalists continue to focus on justification, which is a property for belief that is accessible to the individual, implying an internal faculty for formulating the truth. The externalists focus on properties of belief that are not accessible to the individual but can be observed from without, such as warrant and proper function. To properly function means to work within one's design plan in an environment suitable to that plan. Significant problems attend the concept of proper function, since any account of what it means to properly function requires a theory that itself must be shown to be true. Similar problems attend the concept of warrant, which involves ratifying the underlying presuppositions for a particular belief or action based on a lining up of various external circumstances. The result is a focus on what counts as knowledge for either the individual or the group. This means that knowledge as certainty is abandoned for other definitions such as functional ability to achieve one's goals.

To define knowledge in relation to achieving what one wants is a kind of pragmatism, a movement championed at the turn of the twentieth century by American philosophers such as William James (1842–1910) and John Dewey (1859–1952). While it can be known what means are necessary to achieve a given goal, pragmatism is silent on what goals should be sought. This is because what works is a claim about one's feelings and not about what is real. Pragmatism leads to this kind of skepticism because of its roots in empiricism. Empiricism asserts that knowledge begins in sense data, and analytic philosophers since 1945 have generally viewed sense data as basic in their attempts to construct theories of knowledge and language.

Presupposing empiricism without critically examining it and its attending problems is the common denominator in philosophy (continental and analytic) since 1945. Because of the individuality of sense experience and the inductive nature of all empirical approaches, it has long been noted that empiricism ends in skepticism.

The past centuries of philosophy that have been based on empiricism and the critics of those philosophers who continue to rely on empiricism in their critiques are a testimony to the way patterns work in the history of philosophy. If empiricism leads to skepticism, then the alternatives are to accept the consequences of skepticism or to reject empiricism in favor of an alternative approach to knowledge. Because alternative approaches, such as rationalism, have also failed to arrive at knowledge, an alternative approach must avoid antinomies and instead critically examine the presuppositions behind knowledge claims.

Neo-Orthodoxy Theology

Nineteenth-century liberal theology had assumed that human nature was basically good. The terrible slaughter and destruction during World War I and World War II virtually destroyed

the liberal belief that all but a few humans are good, kind, and gentle. In its place, the theology known as Neo-Orthodoxy posited an infinite gulf between God and humanity created by original sin, which humanity cannot traverse apart from the reconciling work of Christ.

Neo-Orthodoxy was a progressive twentieth-century Protestant theological movement that both embraced post-Enlightenment philosophical perspectives (hence, “neo”) and claimed continuity with the classic Christian creeds (Nicene, Chalcedon, and others) as well as the ideals of the Reformation (hence, “or-

thodoxy”). Due to its amorphous boundaries, the movement was not unified and did not possess a common set of fundamental beliefs. Nevertheless, the major Neo-Orthodox approaches are most easily distinguished by splitting its adherents into two streams: (1) those who accepted a supernaturalist worldview and the factual truth of historic Christian doctrine, and (2) those who rejected a supernaturalist worldview but maintained that historic Christian doctrine was true in a nonfactual sense and needed to be freshly applied to each new generation. The two most prominent representatives of the first stream were Swiss theologians Karl Barth (1886–1968) and Emil Brunner (1889–1966), whose contributions were developed and expanded by Gustav Aulén (1879–1977), C. H. Dodd (1884–1973), and Reinhold Niebuhr (1892–1971). The German theologians Paul Tillich (1886–1965) and Rudolf Bultmann (1884–1976) dominated the second stream, whose ideas were elaborated and given mainstream expression by H. Richard Niebuhr (1894–1962) and John A. T. Robinson (1919–1983).

Foremost among the tenets of the first (or “supernaturalist”) stream was its doctrine of God as an eternally transcendent holy being who is wholly other than humanity and who, with free and complete sovereignty, chooses how to control, redeem, and reveal himself to his creation. Barth and his followers argued that God’s self-revelation comprises the threefold Word of God, which comes to humanity as Christ (the revealed Word), the Scripture pointing to Christ (the written Word), and the sermon that serves as the vehicle for the Holy Spirit (the preached Word). The revealed Word is the Christ of faith, risen from the dead and proclaimed by the apostles, and is not, as for nineteenth-century liberalism, necessarily identical with the Jesus of history. Viewed as a purely human book containing errors and contradictions, the Bible does not itself constitute the Word of God but is a witness to revelation that becomes the Word of God only insofar as God employs it to effect personal encounters with individuals. Similarly, the sermon is not the preached Word unless the Spirit discloses himself to persons in moments of crisis through the language of the pastor.

Barth’s radical view of original sin led him to reject all forms of general revelation (knowledge

Karl Barth was considered the leading Protestant theologian of the twentieth century. Many intellectuals consider the Swiss scholar the most influential Christian thinker since sixteenth century theologian John Calvin. (Library of Congress)

of God learned from nature); however, Brunner took a positive attitude toward natural theology. He believed in the innate ability of humanity to gain knowledge of God by rationally reflecting on creation and apprehending an objective moral law. Inspired by Dietrich Bonhoeffer (1906–1945), Brunner adopted natural theology as a foundation for a socially just ethical system balancing individuality and community. Brunner was followed in this endeavor by German American theologian Reinhold Niebuhr, who forged proximate social answers to human needs that could be accomplished through the manifestation of Christ's redeeming love in believers.

Central to the theology proffered by the second (or “nonsupernaturalist”) stream was Tillich's method of correlation, which first analyzed the human situation to locate its existential questions and then demonstrated that the essential Christian symbols contained the answers to these questions. Denying the existence of a supernatural being outside the universe who created that universe, Tillich redefined God as the suprapersonal ground of being itself and the structure of existence, namely that power of being that is presupposed whenever one queries what it means for something to exist. Heavily influenced by Platonism, Tillich expressed the estrangement between God and humanity as the separation between essential being, or all that any person could potentially be, and existential being, or the actual state of each person that radically fails to measure up to its potential. For Tillich, this existential predicament was overcome by new being, defined as essential being present under the conditions of existence. Tillich argued that Jesus of Nazareth was the bearer of the new being and thus the Christ, who manifested essential being in such a way that it was not overcome by time-space limitations. Because of Jesus's triumph over estrangement (sin), new being is available to anyone who wishes to access it via the courage to be, which Tillich considered the literal truth underlying the Reformation *sola fide* (justification by faith alone).

Bultmann endeavored to reclaim the value of Scripture in an age of skepticism through a program of demythologization, which extracted kernels of truth from the alleged husks of biblical myth. This program, Bultmann insisted,

➤ BARTH AND TILlich

Karl Barth's four-volume, 13-part *Church Dogmatics* and Paul Tillich's three-volume *Systematic Theology* stand as the greatest neo-orthodox contributions to twentieth-century religious thought. In the following selection from *Church Dogmatics*, Barth juxtaposes the radical sinfulness of humanity against the radical grace of God displayed in Christ. Barth says, “The election of grace is the eternal beginning of all the ways and works of God in Jesus Christ. In Jesus Christ God in His free grace determines Himself for sinful man and sinful man for Himself. He therefore takes upon Himself the rejection of man with all its consequences, and elects man to participation in His own glory.”

Owing to the resonance of Tillich's doctrine of God with many scholars, he has been styled “the apostle to the intellectuals.” Tillich expounds this concept in *Systematic Theology* when he says, “The being of God is being-itself. The being of God cannot be understood as the existence of a being alongside others or above others. If God is a being, he is subject to the categories of finitude. . . . Many confusions in the doctrine of God and many apologetic weaknesses could be avoided if God were understood first of all as being-itself or as the ground of being. The power of being.”

Apocalyptic Expectations— Roots and Legacy

Religious Studies departments are growing in the United States and all over the world. Part of this desire to understand religion has been fueled by the bombings of New York City and the Pentagon on September 11, 2001, an apocalyptic event if there ever was one. Within this general upsurge of interest in studying religion, there has also been a burgeoning interest in American society in apocalypticism. Such interest is evidenced in popular culture in movies, music, and books, such as the *Left Behind* series of popular best-selling novels by Tim LaHaye and Jerry Jenkins. The ancient apocalyptic imagination, which arguably has its roots in ancient Persia, is alive and well, and indeed it still gives rise to apocalyptic expectations today.

The Greek term “apocalypse” means “the lifting of the veil.” In religious language it comes to mean a revelation, as in the Revelation to St. John, the last book in the New Testament. Apocalyptic literature, then, deals with secrets and mysteries, usually about the end of time. Often these unveilings come by means of visions and dreams with enigmatic symbolism. Apocalyptic authors usually assume pseudonymity, tend to write prophecies after the event, and write their historical reconstructions in times of distress. Many scholars note that apocalyptic literature has certain resonances as well as dissonances with prophetic literature. While, for example, prophets call for repentance and believe that the world can be saved, apocalyptic writers call for patience and ensure a final victory and new creation, one in which the present world will be destroyed and overcome. The book of Revelation is a case in point, though there are many other ancient apocalyptic texts. Apocalyptic themes can be found in apocryphal books such as 2 Esdras (see chapters 3–14), and in Bible texts such as the

book of Daniel (see chapters 7–12) and the Gospels, as Albert Schweitzer has argued in *The Quest of the Historical Jesus: A Critical Study of Its Progress from Reimarus to Wrede*.

A related topic to apocalypticism is eschatology. Eschatology is the study of the end of the world, particularly in theology. Such reasoning includes questions concerning what will happen to particular individuals, the world, and heaven and hell at the end of time. The question as to when Christ will return and when the Final Judgment will be are also eschatological questions, and depending on how these questions are answered, they can be considered premillennial, postmillennial, or amillennial. But the crucial point to note here is that eschatology refers to a theological endeavor, while the term “apocalyptic” is usually understood to be a genre of literature but, as noted, has other contemporary manifestations as well, as in movies and music.

Ancient sources have inspired the apocalyptic imagination to the present day. In *The End of the World: An Annotated Bibliography*, Tom McIver lists thousands of sources of a wide variety that deal with the end of the world, from works predating 1800 to works up to 2000. One lesson that he took away from his research was that the end of the world has been predicted time and again by various groups, but all such predictions, of course, turned out to be false. Such failures, however, have not stopped new predictions, predictions that are as contradictory as they are violent.

One can observe these contradictory claims and violence in modern-day Israel. On May 14, 1948, the Declaration of the State of Israel was read in Tel Aviv. The timing of this event was no coincidence, because nearly half of the world's population of Jews had been exterminated by the Nazis. The founding of the modern State of Israel, then, was to provide a safe haven for Jews. The declaration appealed to the Hebrew Bible for its justification, for the birth of the Jewish people, according to the Hebrew Bible, was in the land of Israel. Having been forced into exile, the declaration reads, the Jews have prayed for their return. Christian Zionists believe that the founding of the modern State of Israel is in accord with biblical prophecy, that the end times will unfold just

as the book of Revelation has predicted, and they long to see the Temple rebuilt so that the end times will be inaugurated. However, the al-Aqsa mosque is situated on what Christians and Jews call the Temple Mount. Muslims know this place as al-Haram al-Sharif (Noble Sanctuary). The mosque has been closed to non-Muslims since 2000 because of attempts at destroying it. The beautiful Dome of the Rock is also nearby, and Muslims believe that it marks the spot where the Prophet Muhammad ascended into heaven. What exists in this sacred place are competing faith claims over the same space; add an apocalyptic spirit, and there is a deadly recipe for violence.

No one understands what is at stake with regard to apocalyptic expectations today better than Princeton's Richard Fenn. In his recent *Dreams of Glory: The Sources of Apocalyptic Terror*, Fenn argues that Judaism, Christianity, and Islam need to repudiate the apocalyptic elements in their own traditions, both in their theology and in their scriptures, because apocalyptic longings, with their promises of final and complete victory for those who are able to stand the test of time, are, in Fenn's analysis, both the result and the cause of various disasters, such as September 11, 2001. In response to the threat of nuclear annihilation, Fenn is calling for a "unilateral theological disarmament" whereby all religious traditions get rid of their narcissistic sense of superiority. What is particularly interesting about Fenn's critique is that it is aimed at liberal churches that have tended to read the apocalyptic aspects of their traditions metaphorically and existentially, because this has provided theological cover for more literal beliefs with more destructive effects. The liberal churches, in other words, have provided cover for the Pat Robertsons and the Jerry Falwells and for radical Islam.

Whatever one makes of Fenn's call to the churches, it is hard to disagree with his insight that the stakes are very high with respect to the apocalyptic expectations of today. It is appropriate, then, that Religious Studies departments are growing, especially as they turn their gaze to understanding apocalyptic expectations. And if we look with Fenn, we might begin to see through them.

—Nathan Carlin

➤ CHRISTIAN ZIONISM

Christian Zionists are evangelical Protestant Christians who fully support the State of Israel and advocate its right to all of historic Palestine because of their literal reading of biblical prophecies and the role of the Jewish people in them. These Christians believe that Israel's existence fulfills messianic prophecies in the Bible and indicates that the second coming of Christ is drawing near.

The tenets of Christian Zionism emerged in nineteenth-century England in the teachings of two evangelical preachers who promoted the literal interpretations of apocalyptic references in the Bible and developed doctrines such as the rapture. These ideas gained popularity in the United States and, particularly in the last 30 years, have become a major interest of conservative Christian groups, including those led by Jerry Falwell and Pat Robertson.

One of the most controversial Christian Zionist beliefs is that the return of Jews to Palestine will be followed by the near annihilation of the Jews during the end times. Despite this conviction, the Israeli government welcomes the support of Christian Zionists and enabled the International Christian Embassy to establish its headquarters in Jerusalem in 1980; likewise, Christian Zionists and lobbyists for Jewish causes and Israel in the United States have nurtured an alliance since the 1980s.

Liberation Theology

Liberation theology emerged in the wake of Vatican II, principally in Latin America as an attempt to link social concerns for poor people with Catholic practice. In the 1960s and 1970s, important scholarly theologies of liberation were produced, following the lead of Peruvian Gustavo Gutierrez. However, most of the activity of liberation theology emanated from locally organized base Christian communities. These groups, often led by laypersons, discussed biblical passages in an effort to understand the difficult social and political realities of their day. Liberation theology in practice empowered poor people to understand their oppression under national security regimes and on occasion has encouraged them to take political or military action against their oppressors.

The larger scope of Vatican II, which pursued the objective of making the Catholic Church more relevant to the masses, found expression in Catholic discourse in Latin America. In 1968, some three years after the rise of Vatican II, Latin American bishops met at Medellín, Colombia, under the auspices of the *Conselho Episcopal Latino Americano* (Latin American Episcopal Conference, or CELAM). During much of the twentieth century, Church officials had maintained a cozy relationship with Latin American heads of state, many of whom came to power through coups or questionable elections. Bishops at the conference argued for a change of direction, declaring that priests should offer a “preferential option for the poor.” The new theological direction was reaffirmed at a subsequent conference in Puebla, Mexico, in 1979.

Liberation theology grew from a grassroots level, notably in Central America, Brazil, Peru, and elsewhere in Latin America. Versions of the trend appeared in other developing countries across the globe. Base communities were initiated with the help of parish priests, although often enough these were created by laypersons. In one sense, these local collectivities were parallel to the colonial institutions called *cofradías*, lay groups that took responsibility for public homage of Catholic saints who were locally important. The twentieth-century groups focused more squarely on everyday concerns, with a new

The violently repressive actions of the Salvadoran government against its citizens and clergy transformed archbishop Oscar Romero into a crusader for human rights and a critic of U.S. military aid to El Salvador. (Leif Skoogfors/Corbis)

twist: participants were reading and discussing the Bible.

The rise of liberation theology needs to be understood in light of the political situation in Latin America in the mid-twentieth century. Most nations were governed as national security states, strong-arm ruled with the support of a small elite class. The Church generally turned a blind eye to the atrocities of these states, including the harsh treatment meted out by national guards and other police forces. Right-wing dictatorships thrived in much of Central America from mid-century, such as the Nicaragua of Anastasio Somoza. Civil wars broke out there and in El Salvador and Guatemala. Meanwhile, a 1964 military coup in Brazil resulted in a ruling junta that stayed in power until 1983.

Gradually, Catholic priests and some of the hierarchy became aware of and concerned about

the atrocities perpetrated by these regimes. Parish priests counseled numerous peasants who were caught in the crossfire of the civil wars. A few priests, such as Nicaragua's Gaspar García Laviana, even took up arms in support. Mostly, however, parish priests sought avenues of non-violent resistance to the national security states.

Nevertheless, numerous Catholic priests and nuns paid for their support of these local groups with their lives and are remembered as martyrs. The most famous of these was Archbishop Oscar Romero of El Salvador, whose discovery of the social realities of his day are well documented in the feature film *Romero*. After urging Salvadoran soldiers to lay down their arms in a 1980 radio address, Romero was killed in the middle of celebrating Mass. Also in El Salvador, six Jesuits, their housekeeper, and her daughter were slaughtered in 1989. This and other violence was perpetrated by right-wing paramilitary forces as much as by government soldiers.

Among Latin American intellectuals of the 1970s and 1980s, a new genre of publication emerged that reflected these local theologies. Thus, liberation theology is also known as a genre of theological writing by Latin American scholars aligned with the Church. Best known among these was Gustavo Gutiérrez, whose 1973 publication *A Theology of Liberation* is considered to be a seminal text in the field. Gutiérrez and other writers sought to encapsulate the possibilities for liberation in these biblical discussions. Their audience was an academic one, and these works were read throughout the world.

In the last decade of the twentieth century, liberation theology faded out of public view. This was due to several factors. Pope John Paul II, who as a conservative was alarmed by the connection between the Christian Base Communities and left-wing political groups, spoke out against liberation theology and its leaders. He publicly chastised the Nicaraguan priest and minister of culture Ernesto Cardenal on a visit to that country, a rebuke that was not well received by his audience. Toward the end of the century, the political climate in the region stabilized as well. Rebellions in El Salvador and Guatemala subsided, and in Nicaragua the Sandinistas were removed from office in the 1990 election.

➤ BASE COMMUNITIES

Ecclesiastical Base Communities, known alternatively as CEBs or BCCs, were locally based groups of Latin American Catholics who produced and practiced liberation theology in the late twentieth century. The groups were often as not lay led, although sometimes priests would attend. At base these were organized as Bible study groups in which participants sought meaning in biblical passages that would resonate with the difficulties of living under oppressive or restrictive regimes.

In the CEBs, many Latin American peasants learned to read, which in itself was empowering. Biblical passages were discussed with an eye to finding relevance to the world of oppression in which they lived. Several questions were pursued in these groups. How can they view the world as Christians, given the poverty and violence in their lives? What solutions can be found in these communities of faith?

For example, CEB parishioners might discuss the following passage from Matthew 19:24: "It is easier for a camel to go through the eye of a needle, than for a rich man to enter the kingdom of God." They might ask why Latin American society has become so divided between a small elite class and a large class of poor people and how a Christian ought to react to that reflection. Some might go so far as to suggest violent resistance to the regime, although others might cite biblical passages that condemn violence.

Liberation theology and its base communities have not totally disappeared, but their prevalence has greatly diminished since the settlement of Central American civil conflicts, the end of oppressive national security regimes elsewhere in the region, and the increasing popularity of Protestantism especially in its Pentecostal form.

—Rick Warner

Finally, the rise of Protestantism especially in Central American villages offered peasants an alternative to Catholicism altogether. They found Protestantism meaningful for many of the same reasons that liberation theology appealed to them in earlier years: personal relationship to the Bible as text, supportive grassroots-based community, and freedom from the dictates of religious hierarchy.

Structuralism and Post-Structuralism

Structuralism was a twentieth-century intellectual movement that has affected disciplines and challenged the traditional sources of meaning provided by the Western tradition. This tradition provided meaning to the world through transcendent, other-worldly essences that were located in a divine or metaphysical realm, much like Plato's forms or the Christian God.

Structuralism's founders argued that such essences did not exist, insisting that meaning was produced by structures that preceded human consciousness. Meaning did not come down from a divine, metaphysical realm but rather came up from the material structures. These structures, furthermore, changed slowly over

time and determined how human beings acted by limiting the context in which a person lived, a severe blow to the freedom of human agency. One could argue, then, with the French social historian Lucien Febvre (1878–1956) that one could not be an atheist in the sixteenth century because the structures of religious thought did not allow it. Just as important, however, is that meaning did not reside in the structures themselves but instead arose from the differences between the parts in a structure. Thus, the letters "d," "a," and "d"

have no meaning by themselves but do have a meaning when they are combined into a word that manifests the differences in sound. All of these components in a system, moreover, can be assigned a place and a function in relation to the other parts, which inclines structuralism to treat traditionally humanistic topics in a scientific manner. As a result, a structuralist historian does not examine the people or events but instead examines the underlying structures of society that limit a person's actions and thoughts.

Structuralism began in the studies of Swiss linguist Ferdinand de Saussure (1857–1913) who argued that in the sign system of language, a word (sign) links a concept (signified) with a sound or image (signifier). This means that when one uses a word such as "bean," one is not attempting to capture the essence of a bean but instead is merely describing a concept by placing sounds and letters next to each other. The point is that the link between the concept and the sound or image, between the signified and the signifier, is arbitrary. If it was not, then only one language would exist.

Saussure's ideas heavily influenced the French anthropologist Claude Lévi-Strauss (1908–2009), who believes that culture, like linguistics, was built on structures. All cultures, for Lévi-Strauss, have structures for myths and rituals that, in turn, give meaning to human life. While the content of myths and rituals differed, the social significance was the same in that all myths and rituals allowed people to live together in society. These structures, moreover, were always articulated in the form of binary oppositions: for example, female versus male, raw versus cooked, or nature versus culture.

Post-structuralism, which arose in the mid-twentieth century, challenged this binary opposition model, emphasizing instead the interrelatedness and overlapping of the structures of thought. Specifically concerned with the complex relationships of knowledge, power, and discourse, the French philosopher and historian Michel Foucault (1926–1984) argued that power and knowledge were inseparable. In fact, power is spread throughout society in the form of institutions of control (e.g., schools, hospitals, and the military). Experts operate these institu-

France's Jacques Derrida, the leading philosopher of "deconstruction," an important post-structural intellectual movement. (Hulton Archive/Getty Images)

tions by categorizing people, ordering them in their proper place. The people then internalize this categorization and believe that they are what the experts say they are. Ultimately, this means that a person is neither autonomous nor simply created by structures embedded with binary oppositions but instead is culturally constructed through several discourses, or systems of thought, and the many relationships of power and knowledge.

French philosopher Jacques Derrida (1930–2004), another important post-structuralist, did not specifically critique structural anthropology, as Michel Foucault did, but instead critiqued the entire Western tradition of philosophy as well as the structuralists. More specifically, he critiqued those who sought an original source for all things on which to ground their systems of thought. Derrida argued that the entire philosophic tradition was simply the renaming of this original source, this Logos, whether Logos was conceived of as the Christian God, Locke's natural laws, Hegel's Idea, or even the structures of Saussure. Instead of positing another conception of this source, Derrida wanted to break apart, or deconstruct, any attempt to establish a central source or the binaries that described it.

Derrida's method of deconstruction did not allow the existence of an original source. If such a source did exist, he continued, people cannot know it. He contained this argument in his term *différance*, a French pun on the words for "difference" and "to defer." For Derrida, as for the structuralists, difference is important, but unlike the structuralists, for Derrida there is no center or structure. For instance, in language one may trace a signifier (sound or image) to its signified (concept), but one discovers that this signified is also a signifier for another signified. Thus meaning, which arose for the structuralists in the differences between parts, continuously escapes because it is always deferred to the next component. Derrida, however, did not understand his position as endowing meaninglessness. Instead, he saw his method of deconstruction as a way to free people from fixed truths, endowing them with the radical freedom to create their own selves and world.

—James M. King

➤ SEMIOTICS

Semiotics, or the study of signs, arose in the work of the Swiss structural linguist Ferdinand de Saussure. He posited that a word (sign) connected a sound or image (signifier) to a concept (signified) and that this connection was entirely arbitrary. Thus, describing a table with the word "table" is necessary only because "table" is the carrier of meaning that has been agreed upon. This sign is only one of the many signs of a communication system, called a code, that also requires people to agree upon rules that relate signs to one another. These signs are called the code's vocabulary, while the rules are the code's grammar. This code could take any number of forms: a language, air traffic control signals, body movements, games, or rituals, to name only a few. Since these codes do not precede people but are created by them, the values of the people who create the codes are also included in those codes. As a result, by examining a culture's codes, one can determine what is important to that culture. Thus, it is not surprising to learn that semiotics, which originated in linguistics, has often been employed in anthropology and cultural studies.

Postmodernism and Deconstruction

The terms “postmodernism” and “deconstruction” resist easy definition. One difficulty stems from the use of the terms in fields of study as wide ranging as art, literature, sociology, philosophy, architecture, and religious studies. In each of these contexts, the terms have taken on distinct shades of meaning suited to their particular objects of analysis. Yet the more significant complication in defining the terms involves the central idea behind them. Both terms rest on the notion that human concepts do not reflect objective realities. Because concepts have no firm meaning beyond their representation, definitions are inherently arbitrary. The two terms have proven useful in varied intellectual contexts precisely because their very definitions unsettle strict disciplinary distinctions.

Both historically and conceptually, postmodernism followed modernism, a broad approach predicated on at least two assumptions: the existence of objective truths and the increasing ability of humans to access those truths through the continual application and development of tools of scientific and rational analysis. Historians have associated the emergence of modernity with the anti-authoritarian Enlightenment, which valorized critical scrutiny of received knowledge as the gateway to a better future.

But the term “modernism” also belongs to the late nineteenth and early twentieth centuries, when rapid advances in science and industry helped give influential movements of artists, intellectuals, and theologians newfound confidence in humanity’s progression away from traditional beliefs, practices, and standards. Examples of modernism include the architecture of Frank Lloyd Wright (1867–1959), with its rejection of ornate Victorian forms, as well as the so-called higher criticism of Julius Wellhausen (1844–1918), which subjected biblical texts to historical and critical analyses.

Following World War I, various thinkers and artists began laying the conceptual roots of the move beyond modernism. They pointed out that early modernists had not rejected traditional styles and techniques so much as they replaced certain traditions with their own. These later

modernists included both Dadaist and Surrealist artists as well as European intellectuals in dialogue with the work of Søren Kierkegaard and Friedrich Nietzsche. Deeply skeptical of cultural and intellectual convention, they set out to free thought and creativity from the restrictions inherent in conventional systems of meaning and organization.

But even these later modernisms, the Marxist theorist Frederic Jameson (1934–) would lament in *Postmodernism, or, The Cultural Logic of Late Capitalism* (1991), ultimately became subject to “canonization and an academic institutionalization of the modern movement.” Seeking an explanation for the emergence of the postmodernism that theorists began discussing in the 1970s, both Jameson and French philosopher Jean Baudrillard (1929–2007) concluded in the late 1980s that the shift from modernism to postmodernism reflected the transition from industrial to postindustrial society. While industrial society had tended to canonize objects and ideas whose use-value it found superior to those of the past, postindustrial society and its concern for technology, information, and reproduction had replaced use-value with an empty and ahistorical sign-value. In this way, humans had moved from a modern world of reality, in which tangible commodities are produced and consumed, to a postmodern world of simulated hyperreality, comprised entirely of what Baudrillard termed “simulacrum,” copies of copies for which no apparent original exists. Focusing much of his attention on the history of architecture and art, Jameson encapsulates the shift to postmodernism through a comparison between the immediacy of the art of Vincent Van Gogh (1853–1890) and the commodity fetishism of Andy Warhol (1928–1987).

On account of the depthlessness, alienation, and pessimism about human agency that they believe the postmodern collapse of reality has inspired, both Jameson and Baudrillard are critical of its development at the very same time that they help theorize its existence. This has led intellectual historians to identify them as heirs of the German theorists of the Frankfurt School, proto-postmodernists whose best-known works criticized what they saw as the negative influence of modernism and advanced capitalism on

➤ FOUCAULT'S IMPACT ON SOCIAL THEORY

Both because French philosopher Michel Foucault examined a wide range of topics throughout his career and because scholars continue to debate whether or not Foucault changed his position on theoretical issues central to his work over time, his legacy does not admit to easy summaries. Of his diverse contributions to social theory, however, few have proven as influential as his conceptualization of power, which he presented in such works as *Discipline and Punish* (1975).

To be sure, the concept of power and its influence on human society had received attention well before Foucault's best-known works appeared in the 1960s. Max Weber, for instance, had argued that humans exerted power over others through shared or imposed beliefs and values. Karl Marx asserted that certain classes exerted power over others through control of means of production.

But Foucault deviated from both of these models. On the one hand, he broke down binary oppositions between oppressed and oppressor by insisting that power exists everywhere and reaches everyone. On the other hand, he freed the concept of power from its association with either beliefs or resources by locating power in social institutions and their various techniques of power. Foucault therefore deemphasized the power of individuals by situating the supposed power of any given individual in relation to the apparatus of knowledge and discipline that creates, sustains, and perpetuates that power. Importantly, he insisted that power does not merely deny or "exclude and repress," as Marxist and other accounts of power had suggested. Instead, it "produces

A philosopher and historian of thought, Michel Foucault was a controversial critic of some of the fundamental ideas of Western civilization. (Bettmann/Corbis)

reality; it produces domains and objects and rituals of truth."

Foucault's studies of prisons, psychiatric institutions, and human sexuality made profound contributions to the study of institutions and human behavior, even if later interpreters often have found him too rigidly structuralist.

—Daniel Vaca

human freedom, fulfillment, self-understanding, and relationships.

Focusing not on capitalism but on text and language, Jacques Derrida (1930–2004) not only contributed significantly to the theoretical development of postmodernism but also gave it substantial analytical support. As evidenced in *Of Grammatology* (1967), Derrida believed that text provided the clearest examples of the inescapable gap between ideas and symbols in systems of signification. To make his point, he denoted

this inevitable "différance" with the nearly identical term "différance." Through close analysis of différance, he demonstrated that words or symbols neither possess single meanings nor can entirely repress alternative meanings. This approach is the fundamental logic of the deconstruction for which Derrida often is remembered. But he did not limit the relevance of deconstruction to text; he insisted that repressions and exclusions of meaning pervade all aspects of human signification. Even analyses of texts inevitably require

a move beyond them, for systems of exclusion rely on discourses that extend far beyond single volumes. A textual analyst cannot decenter a subject without some perspective on the structures that undergird that subject's assumed centrality.

Deconstruction's opposition to clear categories, hierarchical oppositions, and assumed functions and essences helped refine the core postmodern principle that no beliefs, practices, styles, standards, symbols, or words bear universal truth or meaning. Humans do not reflect objective realities or articulate reliable remedies through their thought, writing, or art; instead, they construct realities, standards, and structures through those activities.

Today, both the postmodern denial of universal truth and its corollary—an affirmation of and respect for difference—pervades academic discourse. Although postmodernism sometimes is seen as inherently nihilistic, its potentially positive logic has proved influential not just in scholarly circles but even among religious groups in pursuit of protection from discourses that they find hegemonic or threatening. Although postmodernism may deny that humans have access to a single reality, deconstruction's insistence that humans can unsettle the hegemony of any assumed reality may provide an antidote to the pessimism that the postmodern principle so often inspires.

Feminism, 1945–Present

Feminism is a movement that aims to redress the social, political, and economic inequality that exists between women and men. It is possible to trace the roots of organized feminism to the suffrage campaigns of the late nineteenth and early twentieth centuries, which are often referred to as the first wave of a growing feminist consciousness. Since 1945, the movement has evolved to encompass various culture-specific ideologies, philosophies, and social theories. The feminist movement has not been homogenous. Rather, feminism has been shaped by the diverse contexts in which it arose. Feminists have never been in agreement on how to locate or combat the fundamental oppression under which women have lived their everyday lives. While the feminist movement has been divided along ideological, racial, and class-based lines, the perseverance with which global feminists have fought for women's equal rights and the variety of theories that they have employed made feminism one of the defining movements of the twentieth century.

In the aftermath of World War II, feminism as a movement became less visible throughout the world. Women continued to agitate for political and legal rights, but in general the movement was fragmented. It was not until the late 1960s that feminism would once again develop a mass following. This second-wave feminism developed from the civil rights and antiwar movements in the United States and from global campaigns for peace and nuclear disarmament. These new feminists recognized that despite the political and legal gains of the first-wave movement, women were still an oppressed group. It was believed that in order to free women from this oppression, what was needed was a revolution rather than the reform fought for by their first-wave counterparts. The overriding concern was no longer merely equal rights for women but liberation from the bonds of an oppressive society. Above all else, it was this basic idea that separated first-wave social reformers from the often radical feminist consciousness of the second wave. Women continued to fight for equality in the workforce and greater access to education,

but the movement took on new issues as well, centered predominantly on a woman's right to control her body. Free access to contraception and the legalization of abortion were the two main issues that characterized the second-wave struggle in the United States, Britain, and Europe.

In the United States, one of the major divisions in the feminist movement was between liberal or equal rights feminism and its more radical counterpart. At the heart of the liberal movement was a quest for equality between women and men and a desire to put an end to gender discrimination and sexism. Liberal feminists tended to emphasize women's subordination in the public sphere. To that end, Betty Friedan, author of *The Feminine Mystique* (1963) and one of the foremost liberal American feminists, formed the National Organization for Women (NOW) in 1966, which pushed for equal rights for women in politics and the workforce and increased access to education. Liberal equal rights groups also then were becoming more common in Britain and Canada, for instance, although these organizations tended to be more socialist in character and focused primarily on the status of working-class women. Regardless, liberal feminists shared the common goal of equality between the sexes and strove to foster an egalitarian society through political action and lobbying campaigns.

In many ways, radical feminism developed as a response to the increasing alienation that many women felt in the male-dominated civil rights and antiwar movements. In contrast to the liberal feminists, the more radical feminists who launched the women's liberation movement believed that true equality between the sexes was not possible, as there was a deeper ideological level on which women were being oppressed. Influenced by the groundbreaking work of Kate Millet (*Sexual Politics*, 1970) and Shulamith Firestone (*The Dialectic of Sex*, 1970), radical feminists named patriarchy as the root cause of women's historical and continued oppression. Members of the women's liberation movement focused their efforts around revolutionizing conceptions of the private sphere. They believed that the personal is political, meaning that it was in the institutions of marriage, motherhood, and

National Organization for Women president Betty Friedan and feminists march in New York City on August 26, 1970. The march commemorated the 50th anniversary of the passage of the Nineteenth Amendment which granted American women full suffrage. (JP Laffont/Sygma/Corbis)

sexuality that male power was most deeply felt and that it was in this arena that the liberation of women first would take place. The practice of consciousness raising, which offered women the chance to speak out and voice their own experiences and concerns, was intended to politicize the private sphere and was an integral part of the radical feminist movement.

The division between liberal and radical forms of feminism was not the only fracture in the movement. Situated alongside and sometimes within the predominantly white middle-class movement, lesbians and women of color began to speak out about their own experiences and to form separate feminist groups. The ideology of second-wave feminism had emphasized

► SIMONE DE BEAUVOIR AND *THE SECOND SEX*

Published in 1949, Simone de Beauvoir's (1908–1986) *The Second Sex* has been one of the most influential feminist texts of the twentieth century. Initially intending to write her autobiography, Beauvoir decided that before she could write about herself she needed to ask, "What is a woman?" What resulted has been subjected to its fair share of criticism, yet it remains a hallmark of feminist theory, its influence still evident in feminist writing today.

A prolific writer of fiction, philosophical essays, and journalism, Beauvoir did not consider herself a feminist when she wrote *The Second Sex*. Indeed, she begins the work by stating that the subject of women is "irritating" and that there has already been "too much" written on the subject. Her work was also not intended to reestablish debate about feminism or even to revive the flagging movement. Rather, Beauvoir intended to examine the condition of women through analysis of biology, history, philosophy, and literature and ultimately to prove that the category of woman was a subjective one. Her conclusions were a radical departure from anything that had been written on women up to that point; the book was both vilified and highly praised when it was first published in France.

The importance of Beauvoir's work to second-wave feminism cannot be overstated. It was Beauvoir who first offered the analysis of women as a culturally and socially constructed Other. As

she famously wrote, "One is not born, but rather becomes a woman." This construction of the feminine form is in opposition to the definition of man as the essence of humanity, or Self. "Self," she argues, can only be defined by what is not-self. Women, as the Other, are therefore defined by the qualities they are seen to lack: education, independent income, and the qualities most often associated with masculinity. In other words, women are defined by the very fact that they are not men. More importantly, women have been required to internalize this definition of themselves as the Other, and it is this acceptance, in part, that has ensured the continuation of women's oppression.

The tendency to blame women for their oppressed condition, as well as the lack of agency ascribed to women historically, has been the predominant criticism of *The Second Sex*. Regardless of this, Beauvoir's ideas have informed much of the theoretical writing of the second-wave feminism, from Betty Friedan's *The Feminine Mystique* to the more radical feminist theories of Kate Millet, Shulamith Firestone, and Sheila Rowbotham. These writers have relied on the idea of woman as a socially constructed category. Beauvoir's ideas regarding woman as the Other have proven to be a powerful basis for a variety of theoretical examinations of women's oppression.

—Caroline Butt

gender—above race, class, and sexual orientation—as the primary site of societal oppression. For this reason, many women situated outside the white middle-class norms felt marginalized and unwelcome in the wider movement. In many ways a precursor to third-wave feminism of today, groups such as the Radicalesbians in the United States (1970) and the Organization of Women of African and Asian Descent (OWAAD) in Britain (1978) recognized the need to create separate spaces in which their own issues could be addressed and debated.

Postfeminism, a term believed to have been coined in the 1980s, is almost a complete repudiation of second-wave ideology and represents a break with the second wave. Still debated and far from being universally embraced, the precise

definition of postfeminism is hard to pin down but is often seen as being a media construct and a backlash against the gains made by second-wave feminists. Nevertheless, many postfeminist writers have critiqued the second wave as contributing to the image of women as helpless and submissive and completely at the mercy of an all-powerful patriarchy. Ultimately, postfeminists view second-wave feminism as contributing to the further victimization of women.

The feminist movement today is one that is characterized by a variety of different ideologies and theories. Perhaps the most important ideologically is what is commonly called third-wave feminism. The third wave not only developed as a critique of second-wave feminists and their tendency to focus on issues that were of importance

to predominantly white middle-class women but also as a reaction to postfeminism. The third wave has been characterized by a realization that women from different socioeconomic backgrounds or cultures have not experienced oppression in similar ways. While liberal second-wave feminists would argue that gender is the predominant site of women's oppression and indeed that it takes precedence over issues of race, class, or sexual orientation, third-wave feminists have consistently fought against this assumption. In doing so, they have added further depth to a movement that has been shaped by a richness of diverse social theories and ideologies.

Queer Theory

Queer theory is a body of thought that has emerged along with the academic study of gender and sexuality that traces its intellectual origins in lesbian and gay studies and feminist theory. Yet this newer school of thought, which did not begin to coalesce until the 1990s, also challenges many of the paradigms of those more established fields. For many, the term "queer theory"—in itself a loaded term taken from an

epithet—signifies a shift away from what is understood to be the essentialist underpinnings of those more traditionally defined fields. Queer theory is radically antiessentialist in that it challenges a notion of homosexuality—and indeed of gender itself—as intrinsic, fixed, innate, and universally present across time and space. Queer theorists instead argue that desires, sexual practices, and gendered identities are performances and enactments rather than expressions of true subjectivity (that is, consciousness). This theory serves to critique the whole notion of identity categories and the norms, codes, or commands that create the rubric of good versus bad (or pathological) sexualities. Queer theorists argue that there is no normal, only shifting norms that others may or may not conform to in everyday performances.

If queer theory has developed out of the intellectual movements of postmodernism, feminist theory, and lesbian and gay studies, it also emerged in the context of late-twentieth-century political alliances and strategies. Beginning in the 1980s, as the gay community faced AIDS and governmental reluctance to address this disease, gay activist groups developed new strategies, exemplified by the work of such groups as ACT-UP—a group in the United States that often staged dramatic agitprop protests—and Queer Nation. Although not necessarily drawing on queer theory explicitly, these groups helped to define the field by emphasizing a non-normative antiassimilationist alternative to traditional identity politics and minority group formations.

Queer theory takes as its primary theoretical and analytic focus the destabilization of the terms "gay" and "lesbian" and the disruption of the category of gender, particularly in terms of how gendered analysis, since the 1960s and 1970s, has often been treated as the appropriate intellectual framework for the study of sexuality. Queer theorists argue that the identity-based theories common to gender studies reproduce the conditions of repression they desire to challenge. For example, to claim gayness is not simply an act of self-revelation but is also a way of corralling sexuality within the framework of a category that only appears coherent but that, when opened up, reveals its instability (e.g., Am I still gay if I sleep with a person of the opposite

sex? Or if I sleep with those of the same sex but only in certain conditions and in certain ways? Or if my self-understanding is of myself as straight?).

Because queer theory understands sexuality as fluid, mobile, and plural, starting with the work of theorist Judith Butler, the concept of performance has been a central one, insisting on the situational and provisional nature of all identity. Thus, the terms “gay” and “lesbian” or even “woman” are not understood as self-evident and essential categories but rather as enactments of subjectivity. In this queer reading of identity, gender is understood as process, acquisition, enactment, and creation. Thus, queer theorists often take as their analytic site the spaces where these performances occur and are highlighted: cross-dressing and drag, for example. Rather than assert a universal humanism (gays are essentially the same as heterosexuals, women are as good as men), queer theory embraces the denigrated and ostracized identities (much as it embraces the epithet “queer”) and sees in these hybrid spaces (the transsexual, the drag queen) possibilities for a more thorough-going critique of normative culture.

Therefore, for queer theorists, the problem is not primarily one of bigotry or lack of tolerance or even homophobia per se. Rather than seeking to normalize gayness, it questions the processes that create the urge to normalize. Thus, queer theorists search for and celebrate moments of sexual subjectivity that appear outside of or resistant to firm categories of unified identity. In this sense it is not about gay liberation but rather is about a wider liberation from preconceived notions and/or categories of gender or sexuality.

Feminist theorists and theorists of race and ethnicity have been among queer theory’s sharpest and most persuasive critics. Both the feminist and race critiques of queer theory focus on the ways in which queer theory often implicitly assumes a white gay maleness as prototypical of queer subjectivity. Both feminists and radical theorists of color have been suspicious of any theoretical framework that rejects the need for an aggressive identity politics, a politics based on a notion of a unified and real identity (gay, woman, person of color, and so on). For many

feminist theorists, queer theory is seen as having eviscerated the centrality of gender to social identity, social power, sexuality and sexual identity, and dethroned gender critique as the cornerstone of the critique of both homophobia and sexism. Queer theory’s relation to the politics and theorizing of racialized identities is no less fraught with difficulties than its relation to feminism and feminist identities. The generalizing tendencies of “queerness” (queer as everything not normatively heterosexual) has the potential to evacuate the specificities of racialized identities in favor of a queer universalism that claims multiracial status without ever seriously reckoning with the ways in which heterosexual dominance depends on certain racial ideologies.

Many queer theorists have taken these criticisms to heart and are attempting to reframe queer theory to pay more attention to structural social conditions, bodily realities, and the lived vicissitudes of race, class, and gender violence.

Modern Psychology—The Post-Freudian Landscape

Psychology in the late twentieth and early twenty-first centuries has had no central school or personality as had been the case with psychoanalysis and Sigmund Freud in the early twentieth century. As of the early twenty-first century, many competing therapeutic and analytic approaches were available, and many different subfields of psychology were recognized in academic contexts, a situation likely to continue.

Behaviorism, or behavioral psychology, remained a strong current following World War II. This field is based on the study of behaviors and does not rely on unobservable abstractions (such as the mind) to explain behavior. It was developed in part to make psychology more of an experimental science with replicable results. American psychologist Burrhus Frederick Skinner (1904–1990) was the best-known proponent of behaviorism to follow early pioneers such as Ivan Pavlov and John Watson. Skinner argued that any organism's behavior is a function of an organism's history of reinforcement (rewards and punishments), and he conducted many detailed studies of the influence of different types of reinforcement. His ideas have been incorporated into education (programmed instruction stems directly from his theory of learning) and applied behavior analysis, which uses principles of behavior developed by Skinner to improve the communication and social skills of autistic children.

The Swiss psychologist Jean Piaget (1896–1980) founded the field of developmental psychology in the 1920s. His detailed observations of children allowed him to develop a theory of human mental development as passing through a series of stages. Other influential developmental psychologists, with their primary contributions to the field, include Lawrence Kohlberg (1927–1987), who developed a theory of stages of moral development; John Bowlby (1907–1990), who developed attachment theory to describe how parents and children form bonds; and Erik Erikson (1902–1994), who divided the psychosocial development of humans into eight stages and is credited with inventing the term “identity crisis.”

Interest in the field of social psychology received a boost during World War II when governments sought effective ways to influence the behavior of large numbers of people through means such as propaganda. When the extent of German atrocities were discovered after the war, social psychology was invoked to explain how large numbers of ordinary civilians could be induced in large numbers to violate their own moral standards. The American psychologist Leon Festinger (1919–1989) developed the theory of cognitive dissonance to explain how people

➤ THE MILGRAM EXPERIMENT

Stanley Milgram (1933–1984) was one of the most influential psychologists of the twentieth century. His most controversial contribution is the Milgram experiment, a pioneering study in the social aspects of obedience to authority. This experiment has been replicated many times and cited to explain episodes from the massacre of Vietnamese civilians at My Lai in 1968 to the abuse of prisoners at the military prison in Guantanamo Bay, Cuba, during the more recent American war with Iraq.

In the classic Milgram experiment, the subject is instructed by an authority figure to help a learner (who is in fact a confederate of the experimenter) memorize word pairs. The instruction process requires the subject to administer electric shocks to the learner for wrong answers. In fact no shocks are delivered, but the learner acts as if they are. The voltage of the apparent shocks increases, and the learner appears to be in ever greater distress. If the subject attempts to stop the experiment or to check on the learner, he or she is sternly instructed to continue by an authority figure.

The Milgram experiment was prompted by claims of the Nazi war criminal Adolph Eichmann that he was not responsible for his behavior because he was following orders. This raised the question of whether blind obedience to authority was a peculiarity of the Nazi regime or whether it was more widespread. In Milgram's initial experiments (conducted at Yale University), all subjects delivered what they believed to be major electrical shocks (300 volts, sufficient to cause seizures), and over half the subjects delivered what they believed to be 450-volt shocks (the maximum dosage used in electroconvulsive therapy). Similar results were achieved in many replications conducted with varied populations all over the world. What the Milgram experiment demonstrated was that contrary to popular belief, many ordinary law-abiding people will inflict pain upon a blameless fellow citizen if instructed to do so by an authority figure.

negotiate the mental conflict of being confronted with contradictory ideas (or situations that conflict with imbedded values). His initial studies were of a cult whose members became even more radical in their beliefs after an initial prophecy (destruction of the earth on a specified date) failed to occur. An influential series of social psychology experiments conducted by American psychologist Stanley Milgram (1933–1984) and continued by Philip Zimbardo (1933–) demonstrated that most people would obey directions from an authority figure even when they believed they were injuring an innocent person.

After World War II, American psychologist Carl Rogers (1902–1987) developed what he called the person-centered approach to psychology while working at a counseling center at the University of Chicago and later applied these ideas based in conflict resolution to areas of social conflict such as the Protestant-Catholic disputes in Northern Ireland. Rogers's work, along with the American psychologist Abraham Maslow (1908–1970), is often given the rubric humanistic psychology. Maslow developed the theory of the hierarchy of human needs, which ranked needs from lowest to highest as physical (air, food, water), safety (security), psychological and social (love, acceptance), and self-actualizing (fulfilling one's unique talents) and argued that needs lower on the hierarchy must generally be fulfilled before an individual will devote much attention to those higher on the hierarchy. Use of psychedelic drugs such as LSD and peyote as an aid to spiritual development was popularized in the 1950s and 1960s by former Harvard University psychologists Richard Alpert (1931–), later known as Baba Ram Dass, and Timothy Leary (1920–1996). The psychedelic movements' insistence on human potential dovetailed with aspects of the humanistic psychology movement.

As the importance of behavioral psychology with its emphasis on rat-in-maze (or, more properly, pigeon-in-cage) experiments peaked in the 1950s, and as the computer age dawned, by the 1970s, experiment-based psychology shifted again toward interest in cognitive psychology. Cognitive psychologists explore mental processes, how humans perceive, acquire, react to, and process information. As with behaviorism,

cognitive psychology has many applications; examples include educational theory, linguistics, neurophysiology, robotics, advertising, and the design of diagnostic systems and of user-friendly products such as buildings, libraries, automobiles and electronic goods.

Besides the cognitive revolution, in experimental psychology, another significant shift in the twentieth and twenty-first centuries has been that from talk-based therapy to the use of psychoactive drugs. Advances in chemistry in the 1950s produced a number of highly effective psychoactive drugs, including tricyclics such as imipramine (Tofranil), an antidepressant, and antipsychotic drugs such as chlorpromazine (Thorazine) and haloperidol (Haldol). These drugs were the first effective treatment for many serious psychiatric disorders, but all carried significant side effects. More recent additions to the psychiatric medical chest include fluoxetine hydrochloride (Prozac) and risperidone (Risperdal). Drug treatment of psychiatric disorders has become the norm, even in very young children, and some worry that many ordinary conditions of life (such as disinterest in school) are being diagnosed as mental illnesses and treated pharmaceutically.

Public Intellectuals on Democracy

As Richard Posner has suggested, public intellectuals are professionals from academia as well as activists or pundits whose analyses of issues of general concern gain media attention. Political freedom affords these opinion makers an opportunity to articulate dissenting positions on issues and influence the policy-making process. Simply put, without freedom, public intellectuals cease to exist. For this reason, intellectuals, particularly in Western nations, have long debated the meaning, value, and extent of democracy. Argu-

ably, this debate took a more public and engaging turn after World War II with the advent of mass media and in the wake of such totalitarian movements as fascism and Stalinism. Postwar democratic discourse has manifested itself in two areas of concern: the mechanisms and distribution of power and the strength of pluralistic political institutions.

The experience of the 1950s, particularly the intense ideological contentions that unfolded with the development of the Cold War as well as the rise of McCarthyism in the United States, brought renewed attention to the question of challenges to democracy and the issue of power and its distribution in society. In the United States, the pluralist movement headed by Robert Dahl rejected arguments that democracy was on the wane by arguing that political power rested on the extent to which citizens participate in the democratic process. Dahl believed that electoral victories, quite simply, amounted to legitimate mandates. The pluralists do not say much about the relation between resource distribution and the capacity to win elections; rather, they suppose that the democratic process must at least meet conditions of public contestation and voluntary participation. Since electoral contests recur often and periodically, political elites presumably play by the rules of the game. Moreover, pluralists presuppose that citizens participate in electing those who would run the government on their behalf. Concurrently, governing elites have an interest in representing the general will. Whether through term limits or electoral defeats, the democratic system ensures rotation in office. Democracy, according to this perspective, is governed by mechanisms to guarantee elite rotation, widespread participation, and the right to organize an opposition.

The liberal pluralist framework opens several avenues of debate. One such line of research examines how resources affect political power distribution. C. Wright Mills, writing in the 1950s, popularized the notion that the power elite often guards its commanding position through self-sustaining networks involving elites from multiple social sectors. The disproportionate power and prestige of the power elite practically assures this group a victory in electoral contests, distancing it from democratic controls. This crit-

➤ DEMOCRACY IN CRISIS?

Robert Putman, the author of *Bowling Alone: The Collapse and Revival of American Community* (2000) and a past president of the American Political Science Association, is not alone about his pessimism regarding modernity and democracy. Two intellectuals with very different persuasions are also skeptical of modern forms of governance. The celebrated Russian dissident Aleksandr Solzhenitsyn, a vocal critic of the Soviet Union prior to its collapse, has described the political problems of contemporary societies—East and West—as disasters rooted in atheism and spiritual crises. To be sure, Solzhenitsyn regards the excessive materialism and individualism of the recent era as two of the most damaging challenges to Western democracies. The well-known American anarchist Noam Chomsky, on the other hand, views with great suspicion the overriding power of the modern state and celebrates the proliferation of grassroots political movements.

—Enrique Pumar

ical position toward liberal democracy formed the pillar of the new leftist movement that followed in the United States. In addition to pluralists and Mills's approach, David Riesman and other skeptics argued a third posture. Riesman noted in the mid-1950s that a new style of indifference among American voters fostered complacent attitudes toward political participation and electoral politics that impeded rather than manufactured policy outcomes. In Riesman's view, consumerism led to a citizenship more concerned with shopping and leisure than political engagement.

Another venue for analysis is the relation between freedom and the possibility of democratic citizenship formation. For Hannah Arendt, whose most enduring works are *The Origins of Totalitarianism* (1951), *The Human Condition* (1958), and *On Revolution* (1962), democratic participation is not a natural predisposition; for democracy to thrive, favorable conditions for civic engagement must be in place. These concerns arose again in Robert Putman's recent *Bowling Alone* (2000), which examines the relationship between social capital, fostered through

informal and formal networks, and democratic competitiveness. Putnam concluded that in the United States, participation in communities has been impoverished in part from the exigencies of modern life. Relative social isolation, while not yet obstructing essential mechanisms of democracy, is certainly changing the rate of democratic activism. In Putnam's view, politics today is characterized by conformity and a constrained participation.

Another line of public debate concerns the autonomy of the state in relation to class interests. At stake here is the overriding concern among European Marxists and intellectuals from developing nations who share Mills's concern about the capacity of state institutions and mechanisms to act independently from the organized interests of the ruling elite. In essence, the question is whether the state in capitalist societies is merely an instrument of elite interests or whether it possesses enough faculties to be autonomous. Instrumentalists such as the Briton Ralph Miliband argue that while the state may not necessarily be a tool of the ruling class, it certainly acts in concert with their interests. This position differs substantially from the structuralist argument of the French Nicos Poulantzas and others who argue that by taking advantage of internal ruling class cleavages, the state develops sovereignty.

A further dimension of democratic discourse relates to the durability and applicability of democratic institutions worldwide. Is democracy the product of Western civic culture, of years of deepening modernization linked to industrial advance as some intellectuals argue, or do other societies regardless of their levels of development and political culture stand a chance to be democratic? Italy's Norberto Bobbio insists that

citizens have a natural tendency to favor representative governments rather than tyrannies. Others insist that democracy is a warrantor of national security. Accordingly, proponents of this view argue that exporting democracy is the best way to combat major social ills that may escalate into violence among deprived populations. This assumption has fueled many efforts for political development and nation building to this date.

Public intellectuals such as Anthony Giddens, S. M. Lipset, Samuel Huntington, and Guillermo O'Donnell have argued extensively about the peculiar trajectories of democracy among developing nations. One important conclusion from this debate is that democratic institutions do not arise out of conditions exclusive to Western societies such as industrialization or the presence of a large middle class. Rather, democracy manifests itself in the context of national conditions. As Amartya Sen so eloquently reminds us, democracy ought not to be the end but instead should be one of several prerequisites to achieve prosperity and development.

Science and Technology

Examining the history of science and technology since 1945 from a cultural perspective leads inevitably to a mixed review. During this period, some of the major promises of science materialized: longer and healthier human lives thanks to technical breakthroughs in medicine and agriculture, an increase in daily comfort for many, and an opportunity to live in a world informed with technology that was once the stuff of science fiction. Yet the dream itself had soured. Under military supervision, scientists and engineers ended World War II in mushroom clouds and ushered in a new age of nuclear dread. Technological enhancement of economic activities has also stretched the earth's capacities for renewal, with the brunt of environmental stress a burden for the poorer nations and the poor within all nations. The blessings of science also have been unequally distributed between rich and poor nations and between the rich and poor within nations. Since World War II, the Western Enlightenment dream of rational control of nature's forces and resources has deteriorated. Yet viewed from a different angle, this period has offered fascinating developments, including a clearer understanding of the geology of the earth (plate tectonics), the new field of genetic engineering and the mapping of the human genome, and the social revolution engendered by the steady advances of computer technology.

Since 1945, ideology, science, and technology have been closely intertwined. Both the United States and the USSR turned to science for symbolic and strategic gains during the confrontation of the Cold War. In the Soviet Union, Josef Stalin's taste for the neo-Lamarckian genetic theories of Trofim Lysenko created a strange warping of agricultural research. To Stalin, Lysenko's theories of acquired or learned characteristics, rather than Mendel's notion of inherited characteristics, provided a better example of the assumed dynamism and the rejection of tradition on which Marxism was based. Soviet scientists who disagreed might be arrested or even exiled, Lysenko's eventual fate after Stalin's death. Military contracts on both sides of the Cold War divide also warped the basic pattern of research and development through this period, as weapons research drew a high percentage of engineers and physicists.

The symbolic confrontation of the Cold War Space Race between the United States and the Soviet Union provided a form of global spectator sport as both sides channeled resources to realize a new adventure for humanity. Yet even this spectacle, which offered new spying opportunities and relied on missile systems of equal value to nuclear warfare, barely masked the underlying weapons race.

Yet such symbolic contests did help to dissolve tensions and provide common ground. Both the USSR and the United States launched

The 1957 Soviet launch of the first satellite, Sputnik, was hailed in the press throughout the world, including the United States, as a great step forward for all humanity.

their first satellites during the International Geophysical Year, 1957–1958, designed as an arena for international cooperation in science. The 1957 Soviet launch of the first satellite, Sputnik, was hailed in the press throughout the world, including the United States, as a great step forward

for all humanity. A similar reaction developed to the success of the Apollo 11 mission of 1969 in which U.S. astronauts first took “one small step” on the moon. The cosmic perspective offered by satellite photographs of the earth also helped spur the environmental movement and the sense of common humanity it enforced. A spirit of scientific and cultural cooperation was renewed again during the Cold War’s interim thaws of détente and glasnost.

Outside the warping influence of the Cold War, post-1945 science and technology have been marked by notable accomplishments. Although the contribution of the deceased Rosalind Franklin was ignored when Nobel prizes were handed out, James D. Watson and Francis Crick’s discovery in 1953 of the double helix structure of DNA was a major milestone. The emergence of genetic engineering abetted by the Big Science effort of the Human Genome Project (1990–2003) that mapped the entire human DNA code continues to generate new biological and medical discoveries and applications.

On an institutional level, the creation of the United Nations in 1945 helped forge bureaucracies such as the World Health Organization (WHO), founded in 1948, with its humanitarian goal of spreading basic sanitation standards and medical care to all parts of the globe. The WHO began with major campaigns to eradicate specific diseases such as smallpox and, with lesser success, diseases such as malaria. It continues to fund campaigns against epidemics such as HIV/AIDS and, more controversially, to broker health policies for member nations.

Basic knowledge in physics continued to accelerate (along with subatomic particles) after World War II. Shortly after the war, physicist Maria Goeppert Mayer developed the shell model of the atomic nucleus that assigned orbital shells to protons and neutrons, much as had earlier been established for electrons. Postwar Big Science funding of large atom smashers or particle accelerators yielded a harvest of long-awaited chemical elements as well as exotic subatomic particles such as quarks and leptons and antiparticles such as antiprotons and antiquarks. These discoveries came in tandem with new theory such as Murray Gell-Man’s equations for strangeness, which successfully predicted new subatomic particles, as well as his equations for charm that predicted new forms of quarks.

Theorists—with some success—continued Einstein’s effort to reconcile the four basic forces (weak nuclear force, strong nuclear force, gravity, and electromagnetism). Sheldon L. Glashow mathematically connected electromagnetism and weak nuclear forces. Yoichiro Nambu’s insight that quarks and all other elementary particles may be composed of strings has led to the most recent effort at synthesis, since dubbed

“string theory” or “superstring theory,” which represent attempts to unify gravity with the other forces of nature.

In the related realm of astrophysics and cosmology, guided by theory, new devices such as radio telescopes and satellite-based sensors revealed new cosmic exotics, including quasars, pulsars, and black holes. Radio telescopes also detected background microwave radiation pervading the universe that provided stunning support for the Big Bang theory. Aided by satellite sensors, further studies of this background radiation led astronomers to the sobering view that detectable matter comprises only 4 percent of all the matter in the universe, with the other 96 percent locked up in dark matter and dark energy. Concerning this missing 96 percent, no scientists, or for that matter theologians, are yet prepared to offer a coherent explanation.

Aided by satellite sensors, further studies of this background radiation led astronomers to the sobering view that detectable matter comprises only 4 percent of all the matter in the universe, with the other 96 percent locked up in dark matter and dark energy.

The digital computer is one of many breakthroughs in electronics that emerged from military development during World War II. While the British built Colossus to decode German radio transmissions, the United States built ENIAC (Electronic Numerical Integrator and Computer) to compute ballistic tables. Both were enormous machines built of vacuum tubes and required hand plugging of wires similar to telephone switchboards. In 1947, Bell Telephone Laboratories introduced the transistor, which replaced the bulkier and less-efficient vacuum tube as the basic switching and amplifying device in computers and other electronic devices. The transistor was later finessed in the 1960s with the introduction of commercially viable integrated circuits that allowed microscopic transistors as well as diodes, resistors, and capacitors to be etched onto semiconducting silicon wafers. Integrated circuits continued to be miniaturized. Noting this, in 1964 Gordon E. Moore outlined Moore’s law, which so far correctly predicted that the density of integrated chips would double each year. This increase of computing power per cubic inch led to the development of increasingly more powerful workstations and eventually personal computers. Along with the Internet, the computer has had revolutionary impact on research and development, reshaping industry, workplaces, homes, and daily lives.

As significant throughout this period, however, has been the increasing authority behind critiques of science and technology. Such critiques, once emanating from a marginal sphere inhabited largely by romantics and crackpots, slowly migrated toward the center. As the twentieth century progressed, the dystopian possibilities of a technologically advanced civilization became more and more apparent. The 1960s counterculture, itself conditioned to a large extent by the technological discovery of the drug LSD, brought a taste for the critique of progress and a questioning of the rational basis of advanced society to the foreground. The development of nuclear power, from the bombing

of Hiroshima to the nuclear accidents at Chernobyl and Three Mile Island, gave proof that physicists, Aladdin-like, had conjured up powers with immense destructive capabilities. Maverick voices such as that of biologist Rachel Carson, with her study of the adverse effects of pesticides on human health and environmental soundness, also called into question the heroic narrative of progress.

Yet the utopian possibilities of science continue to beckon. More recently, the emerging field of nanotechnology, first prompted by a Richard P. Feynman speech in 1959, offers a similar genie-in-the-bottle scenario. Nanotechnology, or the manipulation and assemblage of matter on the atomic level, already has yielded new chemical products. The field has also created utopian hopes familiar to science fiction of infinitely malleable nature along with dystopian concerns about nanobots run amok destroying all life.

Environmental crisis has offered a new opening for thinking about progress in terms other than the Enlightenment's simple goal of the conquest of nature and natural forces. The near universal scientific consensus of human-fueled global warming reached at the United Nations Conference on Climate Change in Kyoto in 1997 and the urging of a dramatic reduction of carbon dioxide emissions is one major example. Global warming provides a powerful lesson that the Enlightenment dream, when connected with the unfettered market and international competition, has proved itself too successful. Science and technology appear to have rendered humanity on its present largely unmoderated course, too powerful to remain a sustainable species. Environmentalism appears as one way to inject an ethical component into the social demands that guide scientific and technological research and development.

—Fred Nadis

■ Introduction: Scientific Developments

Science continues to be a central engine of change in the contemporary world, stimulating new conceptualizations, thought, and possibilities. As such, research is a high priority for governmental funding worldwide. Yet the knowledge gap between scientists and laypeople that C. P. Snow reported in his 1959 lecture “The Two Cultures and the Scientific Revolution” ensures that much that is revolutionary in science is obscured from the general populace.

Nevertheless, the focus of scientific research, at least in part, can be seen as having a historical component. Weapons-related research during World War II proved that atomic energy could be unleashed for weapons as well as for the

generation of energy; following the war, atomic weapons tests also encouraged U.S. government funding of ecological studies of the aftereffects of nuclear fallout on marine ecosystems. Theoretical developments of the 1920s and 1930s in nuclear physics preceded those history-making developments, but the nuances of current nuclear physics—and the hopes placed recently in string theory to mathematically unify all of the basic physical forces operating in the universe—remain somewhat at a removed from the understanding of the general populace.

Scientific revolutions can also lead or follow larger revolutions in thought: the rise of computers and information theory underpinned the

new field of chaos theory with its somewhat postmodern interest in the mathematical study not of regularities in nature but in finding patterns in irregularities, or what might once have been overlooked as simply the unaccountably random. Along with the rise of computing technology, the paradigm shift toward information can be seen as well in Francis Crick and James Watson's 1953 discovery of the molecular shape of DNA and its ability to code information for regulating and replicating cellular-based life. Life, in this regard, can be simply regarded as information. Tellingly, even physicists and astrophysicists have found it useful to incorporate the notion of information as a basic component of the universe along with older notions such as time, space, matter, and energy. In this respect, we can see in the highlighting of the concept of information a kinship between the worlds of physics and biology and larger currents of thought.

—*Fred Nadis*

Particle Physics

Particle physics is the branch of physics that deals with subatomic particles. As the twentieth century progressed, particle physicists deconstructed the atom into ever smaller particles. The German Werner Heisenberg (1901–1976), the Englishman P. A. M. Dirac (1902–1984), and the Austrian Wolfgang Pauli (1900–1958) developed quantum electrodynamics (QED) in the 1920s to explain the interactions between electrons and photons. In the late 1940s and early 1950s, the German-born physicist Maria Goeppert Mayer (1906–1972) developed the shell model of the nucleus, explaining how protons and neutrons occupy orbital shells around the atomic nucleus.

After World War II, a second generation of theorists refined quantum electrodynamics by mathematically renormalizing it and fixing flawed equations that led to infinite results and problems with how to handle the self-energy of particles. The physicists Richard P. Feynman (1918–1988) and Julian Schwinger (1918–1994), both from New York City, independently developed similar theories. The Japanese physicist Shinichiro Tomonaga (1906–1979), working in wartime isolation in Japan, earlier developed a similar system. Freeman Dyson (1923–) showed that the three

theories were mathematically equivalent, which led to the 1965 Nobel Prize in Physics for Feynman, Schwinger, and Tomonaga. The physics community chose Feynman's mathematical notation system over Schwinger and Tomonaga's systems, and his method of graphically drawing particle interactions, dubbed Feynman diagrams, became widely used.

Postwar particle physicists heavily relied on two tools: the particle accelerator to smash subatomic particles into ever smaller particles and the electronic computer to organize the volumes of data from their research. As a matter of national prestige during the Cold War, the U.S. government built ever larger particle accelerators in national laboratories, most of them attached to universities, in an example of what historians call Big Science. In 1954, 12 European nations created the Conseil Européen pour la Recherche Nucléaire (CERN), located near Geneva on the French-Swiss border, that built multiple particle accelerators in a successful postwar effort to revive European research in nuclear and particle physics. The particle physics community has tended to divide into experimentalists who run the intricate experiments and theoreticians who develop mathematical models to understand the results of the experiments. In 2008, CERN brought online the Large Hadron Collider (LHC), the world's largest high-energy particle accelerator. Keeping the 16.7 miles (27 kilometers) long LHC operational has proven to be a challenge, and as of yet it has not yielded new insights.

New subatomic particles had already been found in cosmic ray research, but the postwar particle accelerators revealed dozens of new subatomic particles during the early 1950s. There was little theoretical understanding of how to organize them until 1953, when the American theoretical physicist Murray Gell-Mann (1929–) proposed a new property called “strangeness” for subatomic particles to help categorize these subatomic particles. In the early 1960s Gell-Mann collaborated with the Israeli physicist Yuval Ne’eman (1925–) to devise the eightfold way to group the known particles into a table similar to the periodic table for chemicals. Just as the periodic table successfully predicted the existence of unknown chemicals to fill out the table, the eightfold way successfully predicted new particles

with specific characteristics. By the early years of the twenty-first century, over 200 subatomic particles have been found experimentally.

Theory also predicted the existence of antiparticles, with the same mass as the corresponding particle but an opposite value for the electric charge. When a particle and antiparticle meet, they annihilate each other in a complete conversion of mass to energy. In 1955, the American physicist Owen Chamberlain (1920–) and Italian-born physicist Emilio Serge (1905–1989) used the Bevatron particle accelerator at Berkeley to confirm the theory by creating antiprotons. The two physicists shared the 1959 Nobel Prize in Physics, and numerous other antiparticles have been found since then. In 1995, researchers at CERN succeeded in creating nine atoms of antihydrogen, the first antiatom, that existed for about 40 billionths of a second before being annihilated in collision with normal matter.

In 1964 Gell-Mann proposed a new type of fundamental matter that in turn formed the larger known subatomic particles. Gell-Mann whimsically labeled his proposed matter quarks and antiquarks and suggested that three flavors, or types, existed. The American theoretical physicist Sheldon L. Glashow (1932–), having published a theory in 1960 unifying the weak nuclear force and the electromagnetic force into an electroweak force, took Gell-Mann's work and proposed a new property for quarks, called charm, and the existence of a fourth quark. Since then the number of quarks has risen to six, and quark theory is now part of the standard model. The standard model attempts to combine the four basic forces (weak nuclear force, strong nuclear force, electromagnetism, and gravity) into a grand unified theory. Glashow's electroweak theory is also part of the standard model. Gell-Mann received an unshared Nobel Prize in Physics in 1969, and Glashow shared a 1979 Nobel Prize in Physics. In the 1970s, Gell-Mann expanded his theory of quarks into what he called quantum chromodynamics (QCD).

The Japanese-born physicist Yoichiro Nambu (1921–) also contributed to quark theory and realized in 1970 that quarks act as if they are connected by strings. Nambu and others developed this insight into string theory in the 1980s. String theory gets even smaller than quarks, dealing

with hypothetical vibrating strings that are near the Planck length (about 10^{-33} centimeters or 10^{-34} inches). No instruments can measure objects that small. These strings in turn make up the larger known elementary particles, such as quarks, bosons, and gluons. String theory demands complex mathematics using up to 26 multiple dimensions and provides a promising avenue to the development of a grand unified theory. String theory later combined with supersymmetry to create superstring theory.

In 1956, the physicists Frederick Reines (1918–1998) and Clyde Cowan (1919–1974) detected a theoretical particle called the neutrino at a nuclear reactor at Savannah River, South Carolina. Reines and Cowan had found that the neutrino that is created occurred during the formation of an electron. In 1962 a neutrino associated with the formation of a muon particle was discovered. Neutrino theory in the 1970s predicted that a third type of neutrino, created during the formation of a tau particle, should also exist, though the tau neutrino has not been found experimentally.

The Sun, powered by nuclear reactions, emits neutrinos. In another example of Big Science, scientists built huge underground experiments to detect solar or stellar neutrinos. The radiochemist Ray Davis (1914–) organized the first experiment in the Homestake gold mine in South Dakota. Solar neutrinos that passed through a huge tank filled with chlorine reacted with chlorine-37 isotopes to create argon-37, though scientists were puzzled to detect only a fourth of the predicted number.

Grand Unified Theory in Physics

The search for a grand unified theory (GUT), combining the four known fundamental physical forces of nature into one mathematical model, became an important quest in the late twentieth century. The great English scientist Isaac Newton (1642–1727) mathematically explained the force of gravity in the late seventeenth century. In the nineteenth century the Scottish scientist James Clerk Maxwell (1831–1879) mathematically explained the force of electromagnetism. In the early half of the twentieth century, Albert Einstein (1879–1955) refined the work of Newton with his general theory of relativity. Einstein spent the last quarter century of his life trying to create a theory that combined his own theory with Maxwell's electromagnetism but failed. With the development of quantum mechanics, physicists discovered two more forces of nature: the strong nuclear force, which holds nuclear particles together, and the weak nuclear force, which causes radiation.

Beginning in 1960, the American theoretical physicists Sheldon L. Glashow (1932–) and Steven Weinberg (1933–), as well as the Indian-born and Cambridge-educated Abdus Salam (1926–1996), developed the electroweak theory, combining the weak nuclear force and the electromagnetic force. Tests in particle accelerators confirmed their predictions of a weak neutral current. Their theory also predicted the existence of three vector bosons that, along with the photon, mediate the interactions within the electroweak theory. Experimental physicists using the particle accelerators at the Conseil Européen pour la Recherche Nucléaire (CERN) discovered the three bosons in 1983.

The American physicist Murray Gell-Mann (1929–) proposed the existence of quarks in 1964, later expanding this insight into a theory called quantum chromodynamics (QCD) to explain the strong nuclear force. This theory proposed gluons as the force particles to mediate the strong force. Gravitons have been proposed as the me-

diating particle for the force of gravity but have not been found and are not widely accepted.

The currently accepted and experimentally proven theories are called the standard model. In the 1960s, cosmologists, used to thinking about the vast expanses of the universe, accepted the Big Bang model to explain the origin of the universe and all matter within the universe. The first few minutes of the Big Bang, as matter formed from energy, replicated many of the conditions that the particle physicists studied in their quest for a grand unified theory. Supersymmetry theories emerged from this marriage of the physics of the very large and the physics of the very small, which seemed reasonable to expect, since any grand unified theory had to explain everything from the Big Bang to the smallest interaction between subatomic particles.

The Japanese-born physicist Yoichiro Nambu (1921–) realized in 1970 that quarks act as if they are connected by strings. Further work by Nambu and others led to the development of string theory in the 1980s. String theory deals with hypothetical strings that are near the Planck length in size (about 10^{-33} centimeters or 10^{-34} inches), so small that no instruments can measure them. These strings manifest themselves as the larger known elementary particles, such as quarks, bosons, and gluons. String theory demanded complex mathematics, using up to 26 multiple dimensions, and provided a promising avenue to the development of a grand unified theory. String theory later combined with supersymmetry to create superstring theory.

Multiple grand unified theories have been proposed, many of them based on string theory, but all the theories require experimental proof that can only come from particle accelerators far beyond current technology, extraordinarily precise measurements to detect gravitons, or measurements of the natural abundance of other esoteric particles thought to exist in certain quantities after the Big Bang. Occasionally another fundamental force is proposed, a fifth to add to the known four, but none have ever been accepted by the physics community. The notion of parallel universes, a consequence of quantum theory, is now seriously entertained among sober-minded theorists.

Cosmology—The Big Bang, Inflation, and the Dark Universe

The quest to understand our cosmic origins has engaged humans for thousands of years. For most of that time, this venture has been a strictly philosophical exercise, with stargazers and pontificators trying to fathom our place within the enormity of the heavens. But cosmology has recently crossed a threshold, moving into the realm of a hard and testable science where the predictions of theorists can actually be verified by observers. This shift has been facilitated by advances in technology, including the advent of accurate instruments that are now providing a flood of data to what has traditionally been a data-starved discipline. Armed with a new generation of precision tools, astronomers may eventually fulfill a long-standing dream: to chart the history of the universe, predict its future, and determine its size, shape, age, and composition.

Among the first observations of lasting importance were the redshift measurements of Edwin Hubble in the 1920s, which showed that distant galaxies are moving away from our own galaxy with recessional velocities proportional to their distance from us. In 1929, Hubble announced his findings, which revealed an almost uniformly expanding universe. His work later became one of the main pillars of Big Bang theory.

Thirty-five years later, in 1964, theorists at Princeton University determined that a primordial blast like the Big Bang would have left be-

hind a detectable trace, a residual background of microwave radiation. This radio haze, known as the cosmic microwave background, was soon discovered, quite by accident, by two scientists at Bell Laboratories in New Jersey, Arno Penzias and Robert Wilson. In 1964, Penzias and Wilson were testing a new radio antenna sensitive to microwave frequencies. They kept picking up static no matter which direction they pointed the antenna and were unable to eliminate this low-level noise. Upon learning of the Princeton work, the Bell Labs researchers eventually concluded that their antenna was picking up the faint fading glow of the Big Bang. Penzias and Wilson received a Nobel Prize for this discovery in 1978.

By then, Big Bang theory had gained broad acceptance in the scientific community—largely supplanting the competing steady-state scenario—yet the concept itself was ill-defined. In 1979, physicist Alan Guth provided some theoretical insights into the earliest moments of the cosmic dawn, determining that when the universe sprang into existence, it grew exponentially and explosively in a short-lived burst called inflation, a term that Guth coined. Inflation, he explained, provided the bang behind the Big Bang as well as the outward thrust behind the expansion first documented by Hubble.

Inflation predicts that matter will be smoothly distributed in the universe except for slight deviations from homogeneity (or anisotropies) due to quantum fluctuations that become amplified during the inflationary phase. Although Guth felt confident about the idea, which was later refined by other investigators, he doubted that it would be rigorously tested in his lifetime. On that score, however, history proved him wrong.

While there have been a number of crucial measurements from both space and the ground since inflation was first dreamed up, one experiment stands out: the Wilkinson Microwave Anisotropy Probe (WMAP), a satellite orbiting Earth since July 2001 whose instruments are sensitive enough to discern a millionth of a degree temperature differences in the cosmic microwave background. The anisotropies measured by WMAP closely matched the predictions of inflation. Based on the latest WMAP data, researchers also estimated that the universe is composed

of 4 percent ordinary matter, with just 0.4 percent of that being luminous matter (stars, galaxies, and the like). The rest consists of the ill-understood categories of invisible dark matter (22 percent) and dark energy (74 percent).

The data also pins down the age of the universe (13.7 billion years) and its constituents with unprecedented accuracy. Yet these triumphs are marred by a sobering fact: 96 percent of the universe is almost a total mystery, as we cannot yet describe the true nature of dark matter and dark energy. In addition, it turns out that the luminous objects that astronomers have fixated on for centuries are a sideshow, relatively speaking, comprising less than one half of 1 percent of the entire cosmos.

Therein lies the paradox of modern cosmology: the more precisely we measure the universe, the more precisely we spell out just what it is we do not know. While some might despair over the fact that the overwhelming bulk of matter and energy assumes a mysterious form that we cannot characterize much beyond labeling it “dark,” other practitioners take heart in the fact that the tools at their disposal are finally getting good enough that we can start to understand the known unknowns—such as dark matter and dark energy—and eventually take on the unknown unknowns, the surprises that are almost inevitably lurking around the corner. “It’s a good bet,” says California Institute of Technology theorist Sean Carroll, “that the fun is only beginning.”

➤ ALAN GUTH’S “SPECTACULAR REALIZATION”

Alan Guth had no idea what he was getting into in the late 1970s when, as a young physics postdoc at Stanford University, he embarked on a path that led to his development of the inflationary universe paradigm, now a cornerstone of modern cosmology. In fact, Guth (a professor at the Massachusetts Institute of Technology since 1980) knew little about cosmology at the time, modern or otherwise. The initial problem that he took on, with help from Cornell University physicist Henry Tye, related to magnetic monopoles, hypothetical particles that carry lone north or south poles. Guth and Tye’s calculations suggested that fantastically large numbers of these particles should have been produced in the Big Bang, yet none has ever been detected.

Guth and Tye showed that monopole production would be suppressed if a phase transition in the early universe was delayed by supercooling so that it occurred at a lower temperature than had been assumed (just as supercooled water turns to ice well below its normal freezing point).

Late one night in December 1979, Guth recognized another consequence of supercooling: It would send the universe into a state of exponential expansion. Cosmic inflation—the notion of a fleeting yet explosive growth spurt in the universe’s earliest moments—was thus born. The accelerated growth phase that Guth proposed did not just dilute magnetic monopoles to unobservably low densities. It also solved numerous cosmological puzzles, explaining why the universe is flat, as observed; why it is so smooth; and even why it produced the small departures from complete blandness that eventually generated galaxies and galaxy clusters.

Inflation has passed numerous observational hurdles in the decades since Guth’s original insight. The model has borne up so well, in fact, that University of Chicago cosmologist Michael Turner has called inflation “the most important idea in cosmology since the Big Bang.”

—Steve Nadis

Chaos Theory

Chaos theory, sometimes called the science of complexity, is a new mathematical understanding of physical phenomena represented by systems of nonlinear equations. Classical Newtonian physics predicted that the physical world behaved in a mechanical, deterministic manner, best described by linear equations. Nonlinear equations contain infinite quantities and can often only be solved approximately. The great French mathematician and astronomer Jules Henri Poincaré (1854–1912) realized at the turn of the century that Newton's equations were not always so straightforward and that small differences in initial conditions of nonlinear equations could have dramatic effects when calculating the orbits of planets. The development of computers,

allowing approximate solutions to large systems of equations, enabled scientists to examine nonlinear equations more closely.

The meteorologist Edward N. Lorenz (1917–2008) introduced the term “butterfly effect” to describe his own insight that a small change in initial conditions can have a dramatic effect on later events, or as he titled a 1972 paper, “Predictability: Does the Flap of a Butterfly's Wings in Brazil Set Off a Tornado in Texas?” Because of the nature of chaos, he argued, even the best knowledge of current weather conditions would not enable meteorologists to predict weather too far into the future. Lorenz used computer modeling to illustrate his ideas and developed a set of well-known equations used in chaos theory. Computers became the essential tool of chaos theorists.

The mathematician Benoit Mandelbrot (1924–) coined the word “fractals” to describe physical shapes that have the same jagged shape no matter what scale you choose to use when looking at them. He noticed that his computer-generated color images resembled shapes in nature, such as the curve of coastlines, the patterns in turbulent liquids, snowflakes, blood vessels, and other natural systems that reflect chaotic behavior. In 1979, he developed his Mandelbrot Set to support his theory of fractals, and his 1982 book *The Fractal Geometry of Nature*, with its gorgeous computer-generated pictures of fractals, helped scientists understand that fractals were a fundamental element of emerging chaos theory.

The physicist and Nobel laureate Murray Gell-Mann (1929–) and others founded the Santa Fe Institute in New Mexico in 1984 to promote the study of chaos theory and other implications of complexity. Chaos theory is probably misnamed, since the use of the word “chaos” implies that there are no constraints; in reality, chaotic systems confine themselves to a limited range of behavior. The implications of chaos theory are still in the early stages, but clearly the Newtonian understanding of physical phenomena is being significantly revised. Chaos theory has been applied to almost every area of science, including ecology, thermodynamics, chemistry, astrophysics, biology, economics, cognitive science, medicine, and even political geography.

—Eric G. Swedin

MANDELBROT AND FRACTALS

Benoit Mandelbrot (1924–) developed the mathematics of fractals, which came to be an important way to visualize chaos theory. As a researcher, Mandelbrot consistently sought the patterns and shapes in things, and early in the 1960s he found that his varied interests all came together in the idea of fractals. Mandelbrot invented the word “fractal” by deriving it from the Latin word *fractus*, which means “fragmented.” Fractals often describe irregular shapes and often are self-similar, in the sense that the closer one looks at the fractal, the more similar fractals appear, just on a smaller scale. Computer scientists worked with Mandelbrot, making complex multicolor graphic images of fractals. They noticed that the images resembled shapes in nature, such as the curve of coastlines, and the patterns in turbulent liquids, snowflakes, blood vessels, and other natural systems that exhibit mathematically chaotic behavior. In 1979, he developed his Mandelbrot Set, which supported his theory of fractals. Mandelbrot's 1982 book *The Fractal Geometry of Nature*, with its gorgeous computer-generated pictures, spread knowledge of his insights. After many years working as a researcher at International Business Machines (IBM), Mandelbrot became a professor at Yale University in 1987.

Information as a New Paradigm

Is reality just a massive complex computer program? Can all of reality—atoms, stars, and living things—be reduced down to just bits of information?

In 1948, Claude Shannon (1916–2001), an electrical engineer and mathematician, published “A Mathematical Theory of Communication,” a two-part article in the *Bell System Technical Journal*. Shannon had been attracted to the problem of how to measure noise on a telegraph or telephone line. He developed the idea that any type of communication can be measured if it could be broken down into a series of yes or no questions. Yes or no are only two values, just like true and false in Boolean logic. Shannon coined the term “bit,” for “binary digit,” as a way to represent the answers to these yes or no questions. Any form of communication could be measured in terms of bits. While the title of his paper was about communication, Shannon had really developed a theory of information.

Bits are also the foundation of modern digital computers, where every bit can only have one of two possible values, zero or one. Shannon’s ideas were first used to create techniques in the form of error-correcting codes so that messages could still get through in the correct form even if there was noise on the line. His ideas also helped develop new ways to engage in cryptography, the making and breaking of secret codes.

Within just a few years, Shannon’s ideas were picked up by physicists and used to try to understand the problem of entropy. In thermo-

dynamics, entropy is the idea that any organized system of particles will tend toward disintegration into randomness over time. If you realize that the organization of particles is just information, then entropy is the loss of information. Shannon had already recognized this and included the idea of entropy in his theory, but physicists took the implications of the theory and started to apply it in other areas. From this new point of view, the four-letter sequences found in genes are merely information expressed as physical chemicals, and cells are merely complex forms of information.

In 1997, Stephen Hawking and two other famous physicists made a wager over whether information was forever lost when particles were swallowed by black holes. Black holes are a favorite topic of physicists because they push their equations to the extremes, and the study of this reveals new insights. In 2004, Hawking paid off the wager, having conceded that black holes do not completely destroy information.

In 1992, the term “qubit” was coined, short for “quantum bit.” Taking advantage of the bizarre qualities of quantum mechanics, the qubit can be both partially one or zero. This intellectual leap led to much speculation on building quantum computers that can solve problems that conventional computers cannot solve. This has particular possible utility in cryptography, where present techniques cannot break strong encryption, while quantum computers would be able to do so. Considerable research has been devoted to building an actual quantum computer, but so far the effort remains in the realm of theory.

In the early nineteenth century, the technological development of steam engines led scientists to seek to understand the natural world in terms of energy. The idea of energy, what it was and how it explained different physical phenomena, revolutionized physics. Now the technological development of the digital computer has led scientists to seek a deeper understanding of information and how the idea of information can explain the natural world. It is yet to be seen if the new paradigm of information will be as important as the paradigm of energy two centuries ago.

> PACIFIC RING OF FIRE

The string of volcanoes that extends from Tierra del Fuego northward along the South and North American continental edge through the Aleutian Islands and then southward past Japan to New Zealand has been characterized as the Pacific Ring of Fire. According to the theory of plate tectonics, the volcanoes as well as related earthquakes are a result of the movement of the crustal plates that make up Earth's surface as they converge, diverge, or pass each other laterally. More than 24,000 miles long in its encirclement of the Pacific basin, the Pacific Ring of Fire is generally defined by the edges of the huge Pacific plate. Along this very active boundary, more than 80 percent of the world's largest earthquakes occur. The Mid-Atlantic Ridge and the Alptide belt extending from Java to the Atlantic are the two other major world seismic regions.

The Pacific Plate with a few other smaller plates create borders of instability as they subduct (or descend) under lighter continental plates. This creates deep oceanic trenches, and melting magma forces its way to the surface in the form of coastal volcanic ranges, as on the western coast of South and Central America and the Aleutians. The collisions can also create island arcs such as the Marianas, the Philippines, part of the Indonesian archipelago, and New Zealand. The San Andreas Fault is a transform fault caused by the Pacific Plate grinding past the North American Plate, which creates massive instability. On the ring's edge are some of the most active volcanoes in the world, including Mount St. Helens, Pinatubo, and Fujiyama.

—Thomas Deaton

Plate Tectonics

In 1915 Alfred Wegener proposed the theory of continental drift. Based on the similarity in land shapes, rocks, and fossils on widely separated landmasses, he postulated that for the last 225 million years the continents had been moving away from the former Pangaea (or supercontinent in which all current landmasses had once been gathered together as one). The idea was revived in the 1970s and renamed Plate tectonics. Plate tectonics theory states that the Earth's rigid outer surface known as the lithosphere is broken into about 22 large and smaller plates that float and move above the asthenosphere, or semimolten layer atop the Earth's mantle. These tectonic plates are irregular slabs of solid rock of varying sizes (the largest are the Antarctic and Pacific plates) and thickness (continental ones may be 120 miles thick and oceanic ones as little as 9 miles thick).

The theory has been used to explain the existence of mountains, deep ocean trenches, earthquakes, and volcanoes. As plates diverge, they create midoceanic ridges such as the one stretching from Iceland into the Indian Ocean or the Great Rift Valley of Africa. Their convergence can create oceanic trenches as heavier plates subduct (descend) under lighter continental ones or can fold up mountain ranges such as the Himalayas when two lighter plates bend as they collide. The San Andres Fault is an example of a transform fault in which the North American and Pacific plates grind past each other. Where the boundaries occur, the instability and tension provide an opportunity for volcanism, earthquakes, and violent movement.

Discovery of DNA

In 1962 three molecular biologists were jointly awarded the Nobel Prize in Physiology or Medicine for their work in discovering the structure of the molecule DNA (deoxyribonucleic acid) in 1953. The significance of their achievement was that DNA is the means by which organisms are coded, in terms of both their structure and their function. The result was the birth of a new science—molecular genetics—and a more intimate understanding of life itself.

The three scientists were an American, James Watson; a Briton, Francis Crick; and a New Zealand-born Briton, Maurice Wilkins. They worked on the DNA problem at the University of Cambridge, England, along with a British biophysicist, Rosalind Franklin, who should also have shared the Nobel Prize but died from ovarian cancer in 1958 (the award is not offered posthumously).

In 1943 a Canadian-American team had shown that DNA was responsible for carrying genetic information, but scientists couldn't understand how a simple molecule was able to contain the enormous and varying amounts of information required for coding all of the species of animal and plant comprising life on earth. Thus, the race was on to solve the problem.

As the molecular components for DNA were already identified, it was largely a case of experimentation with models in working out how those components might have fitted together. This process, in itself, revealed that DNA must be a polymer, so its molecular structure was a chain of similar units bonded together. A polymer made perfect sense, because it allowed for indeterminate lengths of DNA molecule, thereby allowing for the information-carrying capacity clearly needed. Franklin's X-ray diffraction pictures of DNA, made in collaboration with Wilkins in the early 1950s at the University of London,

provided important clues to researchers Crick and Watson.

By 1953 the DNA molecule's famous double-helix structure was theorized and then confirmed. The thing that amazed everyone was the beautiful simplicity of the DNA molecule. In essence, it stored genetic information in the form of a double-binary or quadrinary code. This was because it comprised base-pairs, rather like the rungs on a twisting ladder, and each had only four possible chemical combinations: adenine/thymine, thymine/adenine, cytosine/guanine, and guanine/cytosine.

As the coding for all animals and plants comprised sequences of this simple code, it meant that DNA molecules had to be incredibly long to contain sufficient information for building and running even the most primitive organisms. Eventually it was realized that DNA had a trick up its sleeve. It could unzip along its midline so that its base-pairs parted company. This meant that new DNA molecules could easily be constructed by using each half as a jig, or the DNA could convey information by constructing a similar molecule, RNA (ribonucleic acid), to act as a code carrier within cells.

These processes are known as replication and transcription. They are, quite literally, vital processes, as they are behind the phenomenon often described as the life force. They enable organisms to grow and to function. In addition, it is the recombination of DNA coding during reproduction that provides the genetic variety in species to allow for the process of evolution by natural selection. This discovery opened a Pandora's box of possibilities for genetic research and engineering, the implications of which are not yet fully realized.

Human Genome Project

In the mid-1980s, the advent of new gene-sequencing techniques encouraged visionaries

➤ NEANDERTHAL GENOME PROJECT

In the summer of 2008 researchers at the Max Planck Institute for Evolutionary Anthropology in Leipzig, Germany, completed their analysis of the mitochondrial DNA sequence from a 38,000-year-old Neanderthal bone sample. At the same time, they continued to analyze the code for the far lengthier DNA sequencing of the sample bone's cell nucleus. The mitochondrial DNA code has already led these researchers to some conclusions about the evolutionary role of Neanderthals, foremost that it is unlikely that, as has been hypothesized, Neanderthals interbred with the more late-coming ancestors of modern Europeans (early *Homo sapiens sapiens*). Modern European DNA has a much closer match to African than Neanderthal DNA, indicating little or no mixing after the Out of Africa scenario played across Eurasia. The recent data supports earlier conclusions that Neanderthal and modern human's final common ancestry dates back roughly 600,000 years. As the Neanderthal DNA code is further analyzed, the researchers hope to get a further glimpse of Neanderthal lifeways and their variance from that of modern humans.

—Fred Nadis

to begin to promote the idea of sequencing the entire human genome. Individuals at the U.S. Department of Energy (DOE) and National Institutes of Health (NIH) both started to seek funding for such a project. The DOE justified its interest as a continuation of its long-term studies of the effects of radiation on humans and pointed to its experience with multibillion-dollar big science projects. The molecular biologist and Nobel laureate Walter Gilbert (1932–) became an early proponent of the idea and persuaded his fellow Nobel laureate James D. Watson (1928–) of its feasibility.

The Human Genome Project officially began in 1990 as a joint NIH-DOE project, federally funded at \$200 million a year for 15 years. Watson became the first director of the organization, serving until 1992 when the physician Francis Collins took over the job. The project began by sequencing the genomes of simpler organisms, such as *Escherichia coli*, in order to gain experi-

ence and develop better gene-sequencing technologies. Work on the genome of the mouse accompanied intensified work on the human genome. Britain's Wellcome Trust joined the project in 1993, and many other international collaborators joined, with organizations and individuals from over 20 countries contributing. The Internet allowed the collaborators to share and publish their data.

When the project began, scientists knew that the human genome contained about 3 billion base pairs, making up an estimated 50,000 to 100,000 genes. Many of the base pairs are not parts of genes but instead are just debris connecting the double-helix-shaped deoxyribonucleic acid (DNA) molecule together. As the project progressed, scientists were astonished to find that the human genome contained only about 30,000 to 35,000 genes. The project intended to sequence every base pair. The physiologist J. Craig Venter of the National Institute for Neurological Disorders and Stroke disagreed with the conservative sequencing approach of the project, arguing that they should seek out the genes and only sequence them, not everything else. In 1991, a venture capital firm lured Venter away from the NIH to form the Institute for Genomic Research (TIGR).

In 1995, Venter and TIGR announced that they had sequenced the genome of the bacterium *Haemophilus influenzae*, which contained 1.8 million base pairs. They used a shotgun technique, cutting the entire genome into smaller pieces and using powerful computers to match the base pairs at the ends of the fragments. In 1996, the NIH succeeded in sequencing the yeast genome, using their more methodical and more accurate methods. In 1998, Venter raised the stakes by announcing a partnership with the Perkin-Elmer Corporation, which made a sophisticated automated sequencing machine. Venter's new company, Celera Genomics, intended to use 300 of the machines to sequence the entire human genome in just three years for only \$300 million. They planned to publish their results through their own Web site and not the usual GenBank public database and also sought to make a profit from commercial users of the data.

The two projects feuded as their race intensified. A temporary truce allowed the two to

agree to the simultaneous publication of rough drafts of the genome in 2000. In April 2003, the Human Genome Project announced that it had mapped 99.99 percent of the human genome (100 percent was not reachable because people are genetically different from each other), finishing the project in 13 years instead of the originally projected 15 years and coming in under budget at \$2.7 billion. The final genome contained 3.1 billion pairs, making up 35,000 to 40,000 genes. The Sanger Institute in England had done 30 percent of the work, and the political leaders of the United States, the United Kingdom, France, Germany, Japan, and China signed the statement announcing final success. Celera chose not to complete its effort and continued to offer its research via subscription.

Up to 5 percent of the funding for the Human Genome Project was devoted to studies of the ethical, legal, and social issues involved, a unique innovation for a big science project. It is expected that the human genome map will help scientists create new medical treatments. It may also enable the genetic engineering of human beings, stoking fears of a return of eugen-

ics. Besides curing diseases, will people start to modify their own bodies and the bodies of their children?

■ Introduction: Cold War, Science, and Space

The Soviet Union's successful 1957 launch of the first satellite, Sputnik, as a surprise event during the scientist-planned International Geophysical Year created an international sensation, as journalists and public figures worldwide celebrated humanity's apparent maturing with this new ability to enter the heavens. The launch also stirred consternation in the United States, the Soviet Union's rival in the Cold War. As with the events and posturing of the International Geophysical Year, a conflict and cooperation have been the keynotes of international science during the postwar period.

Rival space programs, in tandem with the building of missiles, nuclear weapons, and other weaponry, were major components of the huge government spending lavished on science and technology during the Cold War. The Soviet Union

created entire science cities in Novosibirsk, Pushchino, and Dubna dedicated to government-prescribed research. The United States created vast networks that involved the military, universities, research facilities, and think tanks.

As with the arts, science, in creating communities of like-minded individuals who must collaborate to succeed, has always offered possibilities for transcending national boundaries and identities. The episode of Lysenkoism in the Soviet Union during which Trofim Lysenko's pseudoscientific theories of botany, which appeared to prop up Stalinist ideology, gained Stalin's backing with devastating results in agriculture and in the scientific community, illustrates the dangers of provincialism in science and the advantage of cooperation. Even well prior to the collapse of the Soviet Union, joint Soviet-U.S. space missions

had become common, culminating in the building of the International Space Station during 1998–2000. Other big science projects with an international component include the development of the multinational CERN particle accelerator in Europe, costly nuclear fusion research facilities, and the Human Genome Project. Fittingly, international concern and studies of global warming rely on data first collected during the International Geophysical Year of 1957.

—Fred Nadis

International Geophysical Year, 1957–1958

The International Geophysical Year (IGY) lasted for 18 months, from July 1, 1957, to December 31, 1958, bringing together most of the globe's nations in a concerted scientific effort to learn more about the planet. Its origins go back to 1950, when several prominent geophysicists met at the home of the American physicist James Van Allen (1914–), and Lloyd Berkner (1905–1967) suggested that another international polar year be organized. (The original International Polar Year [1882–1883] had investigated the Arctic re-

gion. The Second International Polar Year, held 50 years later in 1932–1933, also investigated the Arctic and parts of Antarctica.) Within two years, Berkner's idea became a proposal for an IGY in 1957–1958 under the auspices of the International Council of Scientific Unions (ICSU), a body founded in 1931 to foster international cooperation in science. The United Nations Educational, Scientific and Cultural Organization (UNESCO) began to partially sponsor the ICSU in 1947 and lent its efforts to the IGY. In the United States, the National Science Foundation helped fund the U.S. efforts, with considerable cooperation from the U.S. military, under the auspices of the National Academy of Sciences. The IGY was timed to coincide with the peak of the solar activity cycle, when sunspots and solar flares are more frequent. The Englishman Sydney Chapman (1888–1979) headed the global effort.

The advances in technology during World War II gave scientists radar, sonar, rockets, aircraft, and computers to assist in their more peaceful efforts. The main subjects and tools of the IGY included meteorology, geomagnetism, the aurora and air glow, the ionosphere, solar activity, cosmic rays, longitude and latitude studies, glaciology, oceanography, rockets and satellites, seismology, gravimetry, and nuclear radiation. An IGY committee also coordinated the idea of world days, specific times set aside when scientists at numerous places around the globe make simultaneous measurements, such as during the total solar eclipse on October 12, 1958.

In 1954, an IGY committee agreed to an American plan to launch artificial satellites to orbit Earth as sensor platforms during the IGY. Sergey Pavlovich Korolev (1907–1966), the chief designer of the Soviet ballistic missile program, used the impending IGY to persuade the Soviet government to build a launcher and satellite to preempt the United States. The project was kept secret, and the United States did not even know that a competition was going on until the Soviets surprised the world by launching Sputnik I on October 4, 1957. In their haste to beat the Americans, the Soviets made the first satellite quite simple, with few scientific instruments.

The first successful American satellite, Explorer 1, was launched on January 31, 1958. The satellite discovered zones of radiation around

► CHARLES DAVID KEELING AND GLOBAL WARMING

American chemist Charles David Keeling's (1928–2005) early findings from his research on carbon dioxide at Mauna Loa in Hawaii led to the first warnings in regard to the greenhouse effect and global warming in the 1960s. Dr. Keeling's early research was based on his collection of carbon dioxide samples, through which he established a pattern of increasing levels over time. By 1961, Keeling presented his results using the Keeling Curve to illustrate how carbon dioxide levels were rising over long periods of time, in spite of the response from plant growth in its absorption during certain seasons. This early report led to warnings of the greenhouse effect and its dangers by the mid-1960s. As a result, the Keeling Curve remains an important contribution to the development of understanding the current phenomenon of global warming and its debate among the scientific community.

—Abraham O. Mendoza

Earth, later named the Van Allen Radiation Belts in honor of the creator of the onboard scientific instrument that detected the radiation. Scientists later learned that Earth's magnetic field created these belts of radiation and that the belts helped protect Earth from some of the more harmful effects of solar radiation.

In the run-up to the IGY, explorers swarmed onto Antarctica, setting up dozens of camps and monitoring stations. The naval and military forces of many nations participated in establishing these bases, some of which have remained manned and useful. The IGY also prompted the negotiation of a 1961 Antarctic Treaty, which declared Antarctica the possession of no nation and set the frozen continent aside for scientific study.

A total of 67 nations participated in the IGY with the notable major exception of China, which withdrew from its initial efforts. John Tuzo Wilson (1908–1993), the Canadian geophysicist who later played an important role in the theory of Plate tectonics, was president of the International Union on Geodesy and Geophysics during the IGY and played an important leadership role. China invited him to visit them during the IGY, and he gained some limited informal cooperation. Measurements of geomagnetism on the ocean floors during the IGY contributed to the development of the theory of plate tectonics in the 1960s. Eighty-six vessels participated in measurements of the planet's oceans and seas.

Scientists began the systematic monitoring of the planet's ozone layer during the IGY, creating an important base of information when chlorofluorocarbons became an important environmental issue in the 1970s. The fallout from open-air nuclear testing was also more carefully monitored during the IGY, leading to alarm over the higher than expected levels and contributing to the creation of an open-air test ban treaty in 1963 between the United States and the Soviet Union.

The IGY was followed by the International Geophysical Co-operation of 1959, which allowed the organized tapering off of IGY activities. Many organizations and efforts, such as those in Antarctica, continued after the IGY on a reduced scale, and the organizational effects of the IGY are still felt today. Both the Americans and Soviets embarked on vigorous space programs as part of their Cold War ideological struggle. The

IGY also inspired other smaller-scale efforts, such as the International Years of the Quiet Sun (1964–1965) and the International Decade of Ocean Exploration (1970–1980). Among the efforts directly sponsored by the ICSU was the International Biological Programme (1964–1974).

The Hydrogen Bomb and the Politics of Fallout

During World War II, émigré scientists in the United States, including German Jewish physicist Albert Einstein, learned of National Socialist Germany's atomic weapons development program and urged that the United States develop

The first U.S. hydrogen bomb, known as "Mike," is tested in the Pacific Ocean at Eniwetok Atoll, Marshall Islands, on November 1, 1952. (U.S. Air Force)

► BIKINI ATOLL

Bikini Atoll, the northernmost atoll of the Marshall Islands, was used as a test site for nuclear and thermonuclear explosions by the United States between 1946 and 1958. More than any other test site, Bikini came to public attention with media coverage in 1946. The Operation CROSSROADS tests of 1946 demonstrated the might of atomic explosions on vessels located in the lagoon and brought the mushroom cloud to the public eye. Much discussed during that year, the tests inspired Louis Réard to name his new bathing costume design after the atoll.

Bikini achieved notoriety in 1954 when radioactive fallout from Castle Bravo, the first of a hydrogen bomb test series, contaminated a much larger area than expected, making the nearest atolls—Rongelap and Ailinginae—uninhabitable for years. The native population suffered from radiation sickness, as did the crew of the *Lucky Dragon*, a Japanese fishing boat cruising outside the security area. The U.S. administration received much criticism for its attempt to belittle the implications of fallout on the Marshall Islanders and the Japanese fishermen. Nuclear tests became a major issue of public concern and of international politics, leading to test moratoria in the 1950s and finally to the Limited Nuclear Test Ban Treaty, signed by the United States, the Soviet Union, and Great Britain in 1963.

The four test series conducted at Bikini left the atoll contaminated and uninhabitable. The population of Bikini, which was evacuated in 1946, has not yet been able to return permanently to the islands.

—Ulrike Wunderle

similar weapons. Their warning led to the Manhattan Project, a massive undertaking in which the world's first atomic weapons were produced and used in 1945. As early as January 1944 Edward Teller, one of the Manhattan Project scientists, believed that the fission weapons being developed in the New Mexico desert were not powerful enough. Teller began to theorize a far more powerful thermonuclear device that would rely on an atomic bomb to ignite and trigger a fusion reaction of hydrogen.

After the successful Trinity plutonium fission bomb test and the bombings of Hiroshima and Nagasaki in 1945, the arms race with the Soviet Union began in earnest. The Soviet Union successfully detonated its first atomic bomb in 1949. With this Soviet success as a backdrop, in the United States Teller again began to make his case for the hydrogen bomb. Despite the opposition of 12 of the leading physicists in the United States, including Robert Oppenheimer who had headed the Los Alamos laboratory for the Manhattan Project, in January 1950 U.S. president Harry Truman approved the development of the hydrogen bomb. The successful design involved placing a fission bomb within a larger casing. The intense radiation from the fission reaction would begin the fusion reaction, releasing even greater energy. The first American electronic computer, the U.S. Army's ENIAC (Electronic Numerical Integrator and Computer), aided Teller and others in the planning. Approximately three years after Truman's initiative, on November 1, 1952, the United States detonated its first hydrogen bomb, "Mike," on the South Pacific Eniwetok Atoll. Within a year, under the guidance of the scientist Andrei Sakharov, on August 12, 1953, the Soviet Union successfully detonated its own hydrogen bomb. The Soviet Union's hydrogen bomb had been several years in the planning. Sakharov, later to become one of the Soviet Union's leading political dissidents, was given the Stalin Medal and named a Hero of Socialist Labor.

The global public slowly learned of the dangers of nuclear weapons and radioactive fallout. A U.S. H-bomb test on the Bikini Islands in July 1954 inadvertently exposed the crew of a Japanese fishing ship, the *Lucky Dragon Number Five*, supposedly well outside the danger zone, to atomic fallout. All of the crew sickened immediately, and at least half of the 23-person crew eventually died from complications probably related to exposure. Other fallout-related health problems were reported for populations on other atolls in the Marshall Islands near Bikini. News of the *Lucky Dragon* incident infuriated the Japanese public; a protest group there quickly gained 20 million signatures on a petition urging the banning of nuclear weapons.

Similar protests developed in Western nations. In 1955 Einstein and Bertrand Russell co-

signed a manifesto urging a ban on nuclear weapons. In the manifesto they stressed the dangers of fallout, noting that “it is feared that if many H-bombs are used there will be universal death, sudden only for a minority, but for the majority a slow torture of disease and disintegration.” In 1957, two years later, 22 scientists gathered at the Pugwash Conference in Nova Scotia and issued a statement urging the governments of the world to renounce warfare. In that same year the first protests were staged at the Nevada atomic test site outside of Las Vegas, and the Committee for a Sane Nuclear Policy (SANE) was organized. In the spring of 1957 Australia refused to allow Great Britain to explode a test hydrogen bomb in Australia, and Britain instead chose Christmas Island for its first test. In 1958, more than 11,000 scientists signed a petition presented to the United Nations to end nuclear testing. By the late 1950s Sakharov also began writing of the dangers of nuclear fallout and of atmospheric tests.

Others insisted that nuclear war was indeed an option and that the nuclear weapons race ensured deterrence. Herman Kahn, the RAND Corporation strategist and polymath, published *On Thermonuclear War* (1960), which argued that a thermonuclear war was winnable; his book also provided different scenarios for nuclear war and its aftermath. Civilization, he argued, could survive. “War,” he commented, “is horrible. There is no doubt about it. But so is peace. To some extent, the horrors of war are only an increase or intensification of some of the familiar horrors of peace.”

In 1963 after the nuclear brinkmanship of the Cuban Missile Crisis, the United States and the Soviet Union signed the Partial Test Ban Treaty ending aboveground nuclear bomb tests. In 1968 Sakharov distributed his own manifesto urging peace between the Soviet Union and the West.

Nuclear Weapons Strategy

The development of nuclear weapons after the end of World War II by the major antagonists of the Cold War and their respective allies led to the establishment of specific strategies in dealing with the threat of their use by the other side. Both the United States and the Soviet Union developed huge stockpiles of these weapons from the late 1950s to the 1980s in addition to intricate delivery systems. The threat of using nuclear weapons as a deterrent, ensuring that the other side would respond in kind, known as Mutual Assured Destruction (MAD), was seen as a means to prevent full-scale nuclear war. However, both sides also sought to outmaneuver the other by circumventing this arrangement through the development of newer weapons systems capable of overwhelming the other side’s nuclear weapons.

At the end of World War II the United States held a monopoly on nuclear weapons, which at this time were atomic weapons and had been used to bomb Hiroshima and Nagasaki in August 1945. This monopoly ended in 1949 with a successful Soviet experiment of its first atomic bomb. This led to the United States developing thermonuclear weapons (hydrogen bombs), exponentially more destructive than atomic weapons, by 1952. The Soviet Union successfully tested its own the following year.

Initially, nuclear strategy relied on dropping such weapons from large bomber aircraft, such as the U.S. B-29 Superfortress. The policy of massive retaliation, supported by the Dwight D.

➤ NUCLEAR PROLIFERATION AND NONSTATE ACTORS

Over the past decade, speculation has increased that global terrorist networks, such as al-Qaeda, are working toward purchasing nuclear devices or materials necessary for their construction. The increasing amount of missing sources of depleted or active uranium and plutonium, particularly from Russia, has led many intelligence agencies and government ministries the world over to voice concerns about the growing threat that a nonstate actor might now have a viable weapon. The use of an actual nuclear device or a dirty bomb (made from depleted radioactive material) in a major urban area is a genuine fear given the number of cases in which individuals, among them Russian mafia and Muslim extremists, have been apprehended with or trying to purchase such material. This contrasts with past fears of nuclear annihilation from an actual nation-state exercising its military capability. Nonstate actors with radical political and religious ideologies, acting clandestinely and with no warning and few scruples, offer a new threat for nuclear warfare in the twenty-first century.

—Abraham O. Mendoza

Eisenhower administration, aimed at a first strike against the Soviet Union in case of an attack on Western Europe, relied primarily on the delivery of nuclear devices through bombers. However, as both sides developed huge stockpiles of nuclear weapons and newer delivery systems such as missiles and long-range bombers, such a strategy seemed less effective. While tactical nuclear weapons (for use in the battlefield) continued to be developed, those geared toward the destruction of enemy nuclear weapons deployment and population centers became the standard.

Through the late 1950s to the 1980s, MAD (or nuclear deterrence) structured a nuclear war into two stages, the first strike and the second strike. The first strike would be a first attack by one of the major antagonists on the other. The second strike would be when the attacked state would respond in kind. Given this scenario, both states would be utterly destroyed after this nuclear engagement. According to this paradigm,

a nuclear war would be so devastating and destructive that it would be avoided by both sides. However, if one of the antagonists had the capability of a first strike in which the attacked state's ability for a second strike was destroyed, then it would ensure that the balance of MAD was circumvented.

Circumventing MAD led to the development of more intricate and complex nuclear delivery systems such as clandestine missile silos, intercontinental ballistic missiles (ICBMs), antiballistic missiles (ABMs), submarines equipped with missiles, and long-range bombers. The United States developed the Multiple Independently Targetable Reentry Vehicle (MIRV) as a weapons system specifically designed to circumvent MAD. One ICBM would hold many MIRV warheads that would deploy independently from the missile, thereby destroying enemy targets and nuclear capabilities in a first strike and preventing a second strike. Another means for circumventing MAD was the establishment of the nuclear triad strategy, which meant having a nuclear arsenal of three major delivery components. In both the United States and the Soviet Union, this triad included strategic long-range bombers, silo-launched land missiles, and submarines armed with ballistic missiles. In the event that one or even two of these components were destroyed in a first strike, the third leg of the triad would remain and ensure a second strike by the attacked state.

The end of the Cold War in 1991 lessened the immediate danger of global nuclear war and ended the stalemate between the superpowers. At the end of the Cold War, both the former Soviet Union (including Russia and other break-away republics) and the United States drastically reduced the amount of deployed nuclear weapons, eliminating huge stockpiles of such weapons systems en masse. However, the danger of nuclear weapons or materials necessary for their construction falling in the hands of nonstate actors or being developed by rogue states offers a new threat for a post-MAD world.

Atomic Power and the World's Navies

The U.S. Navy pioneered the use of atomic power for naval propulsion through the development of nuclear-powered submarines in the late 1940s and early 1950s. Admiral Hyman G. Rickover, known as the “Father of the Nuclear Navy,” was in charge of the design and construction of USS *Nautilus*, the world’s first nuclear-powered submarine, that was launched in 1954. The use of nuclear propulsion expanded to include aircraft carriers as well as submarines in the navies of the Soviet Union, the United Kingdom, France, and China. The use of nuclear-powered naval vessels peaked at the end of the Cold War in 1989, although significant numbers remained in operation or production at the beginning of the twenty-first century.

In 1945 many naval analysts saw atomic power as the solution to the problem of the true submarine. Prior to nuclear propulsion, submarines used diesel-powered engines for power while running on the surface and electric batteries while submerged. As a consequence, a submarine could remain submerged only as long as its batteries retained their electrical charge. A submarine needed to surface in order to use its diesel engines and recharge its batteries, a requirement that limited the submarine’s ability to avoid detection by the enemy over the long term. Nuclear propulsion promised to provide a submarine with the ability to remain submerged indefinitely. In simplest terms, a nuclear reactor produces heat that is used to generate steam, which drives a steam turbine for propulsion. Unlike the diesel engines on older submarines, a nuclear reactor required neither fresh air nor a means to exhaust fumes, and therefore the time that a nuclear-powered submarine remained submerged was limited only by its ability to keep the internal air oxygenated and the crew supplied. A nuclear-powered submarine promised to run out of food before it ran out of fuel.

By 1989 there were more than 400 nuclear-powered submarines in service or under construction. With the end of the Cold War and the

➤ RUSSIAN SUBMARINE *KURSK*

The crew of the Soviet nuclear submarine Kursk stands on its rear deck on June 30, 2000. The vessel sank in the Barents Sea in August, killing 180 crew members. (Reuters/Corbis)

In August 2000 the nuclear-powered Russian submarine *Kursk* sank in the Barents Sea as a result of damage sustained from two explosions in its forward torpedo room, the second of which registered on seismographs across Northern Europe. All 118 members of the crew died despite rescue attempts by teams from Norway and the United Kingdom. A Dutch team later raised the *Kursk*, and the official investigation determined that problems with experimental torpedo warheads caused the first explosion, which in turn detonated surrounding warheads in a blast equivalent to three to seven tons of TNT.

While contemporary observers viewed the incident as emblematic of the state of the post-Soviet Russian navy, the loss of the *Kursk* ironically took place during the largest summer drill for the Northern Fleet since the breakup of the Soviet Union. The *Kursk*, commissioned in 1994, was the last of the large (four stories high and more than 500 feet long) Oscar II-class attack submarines designed and approved by the Soviet Navy. During the 1990s many Russian submarines were left to rust in docks along the Barents Sea, and sailors went years without being paid. Although a successful reconnaissance mission in the Mediterranean by the *Kursk* in 1999 signaled renewed military investment, the loss of the submarine rekindled doubts about the post-Cold War prowess of the Russian Navy.

—Jonathan Hagood

subsequent reduction in weapons programs, defense spending, and the size of the navies of the United States and the former Soviet Union, the one-time adversaries scrapped or canceled production of more than half of these submarines. Beginning in 1950 the Soviet Union had built 248 nuclear submarines and 5 naval surface vessels. Russia's post-Soviet navy operated around 60 vessels with nuclear propulsion. By 1993, the U.S. Navy had accumulated more than 5,400 accident-free reactor years. Its post-Cold War navy included more than 80 nuclear-powered ships. The French and British navies included nearly 20 nuclear-powered submarines each at the height of the Cold War, and China launched less than 10 nuclear-powered submarines in the last two decades of the twentieth century.

Nuclear navies also included aircraft carriers. In 1960 the United States launched the first nuclear-powered aircraft carrier, USS *Enterprise*, that was powered by 8 reactor units. By 2005 the U.S. Navy included 20 nuclear-powered Nimitz-class supercarriers. The Soviet Union maintained nuclear-powered helicopter carriers during the 1970s and 1980s. In 2001 the French Navy commissioned its first nuclear-powered surface ship, the aircraft carrier *Charles de Gaulle*. Nuclear-powered aircraft carriers had the advantage of providing more fuel storage space for its aircraft and support ships.

Big Science through the Cold War

“Big science” is a phrase used to describe a pattern of large-scale funding for large-scale scientific research that first emerged during World War II. Prior to this period, scientists often worked individually, in independent laboratories, or in small networks of interrelated research centers. During World War II, however, U.S. gov-

ernment officials organized large numbers of research scientists and technicians for the purposes of developing the first atomic bomb. This effort, called the Manhattan Project, involved over a dozen Nobel laureates and cost approximately \$2 billion. The institutional relationships forged during the war facilitated the continuation of big science activities throughout the Cold War. Not all scientists welcomed the shift toward big science with the qualities that came with it: the focus on funding, expanding layers of administration in science, and, in the early years, its relationship with weapons-related research, as atomic bomb development gave way to hydrogen bomb development and later the neutron bomb.

Through weapons-related research, academic scientists established vital connections with military and industrial interests as well as governmental support that allowed for a wide range of research. Federal funding of university-based scientific research increased from \$1.3 billion in 1963 to \$10 billion in 1989 when, as most scholars suggest, the Cold War ended. While physicists received a disproportionate amount of attention, others in the physical, biological, and social sciences gained from the expansion of big science. American research laboratories that supported their labors include the Oakridge National Laboratory, the Brookhaven National Laboratory, and the National Institutes of Health as well as university-housed and federally supported centers such as the Stanford Research Institute, MIT's Lincoln Laboratory, and the University of Chicago's Argonne National Laboratory.

During the Cold War era, the Soviets established large science cities in Novosibirsk, Pushchino, Dubna, Obninsk, and elsewhere that employed thousands of researchers who worked together on big science projects. Whatever the pursuit or discipline in question, big science typically came with a culture and infrastructure. The culture has typically leaned toward the industrial and bureaucratic rather than the academic and independent. Bigness in Soviet science translated into an industrial-styled organization of the largest community of scientists in the world, with a highly centralized bureaucracy, that was directed by a small corps of powerful leaders.

Although tensions prevailed between superpowers during the Cold War, American and Soviet scientists collaborated on several occasions, including the International Geophysical Year (IGY) studies of 1957–1958 and missions to space. The IGY involved scientists from 67 countries. Their work coordinated global observations in meteorology, oceanography, glaciology, and many other areas. The IGY yielded the collection of novel scientific data, the launching of satellites, and the Antarctic Treaty that required countries to recognize the continent as an international territory for science research. U.S.-Soviet cooperation in space came largely after a period of intense competition over the race to the moon that ended in 1969. In the 1970s, following America's lunar landing, U.S.-Soviet cooperation began with the Apollo-Soyuz Test Project (ASTP). The project tested compatible docking systems between their spacecrafts and facilitated peaceful space exploration agreements between the two nations. Collaborations slowed during the 1980s, as frosty relations developed after the Soviet invasion of Afghanistan, but were revived in the 1990s with the design and development of the International Space Station and \$650 million in NASA commitments to collaborate with Russian science organizations.

Common to all big science projects is the expensive equipment or the large grants necessary for conducting grand-scale studies. In the case of physics, accelerators require large amounts of space and power and large staffs to run research studies on elementary particles. The Fermi National Accelerator Laboratory (United States) and the multinational CERN (European Union) represent two such examples of big physics facilities. In the case of the biological sciences, the Human Genome Project received extensive funding from the American National Institutes of Health and the Department of Energy. Hundreds of millions of dollars, thousands of scientists, and hundreds of centers throughout the world contributed to the big biology sequencing of the code during 1990–2003. Eighty percent of the research and support for the project came from the United States and Europe, along with 5 percent from Japan.

With the end of the Cold War came a shift in support for big science, particularly in the area

➤ ENHANCED RADIATION WEAPONS—NEUTRON BOMB

More commonly known as the neutron bomb, the enhanced radiation weapon (ERW) was a tactical nuclear weapon designed in the United States with the intention of only destroying life while minimizing property damage. An ERW is designed to release energy as neutron radiation, which has lower explosive power than thermonuclear weapons but is still capable of annihilating enemy troops. The concept was originally conceived in 1958 at the Lawrence Livermore National Laboratory in California and was first tested in 1963. President Jimmy Carter halted development in 1978, but it was continued by President Ronald Reagan in 1981. Eventually, with the end of the Cold War in 1991, the project was discontinued, and the weapons were eventually dismantled. While devised as weapons to minimize infrastructural damage (and thus eliminate the widespread destruction associated with nuclear weapons), they still illustrate the employment of big science to develop weapons of mass destruction in the midst of the Cold War.

—Abraham O. Mendoza

of high-energy physics, as evidenced in the mid-1990s in the U.S. decision not to fund the creation of a superconducting supercollider. At around the same time interest shifted toward nanotechnology, research on elements as small as 1 billionth of a meter, with the National Nanotechnology Initiative begun in 2000 and American government funding in this area approaching \$1 billion annually.

➤ TROFIM LYSENKO

The biologist Trofim Denisovich Lysenko promoted a theory of non-Mendelian genetics that found favor in the Stalinist Soviet Union and distorted the science of biology in that country for decades. Born to peasants in Karlovka, Ukraine, in the old Russian empire, Lysenko earned a doctorate of agricultural science in 1925 from the Kiev Agricultural Institute and then worked at the Gyandzha Experimental Station in the Caucasus until 1929, when he moved to the Ukrainian All-Union Institute of Selection and Genetics in Odessa.

A well-known figure in Soviet agriculture, the plant breeder Ivan V. Michurin (d. 1935), argued that plants adapt to their environmental conditions by acquiring the characteristics that they need. This revival of Lamarckianism was more compatible with Marxist ideology than was Mendelian genetics. Lysenko adopted the ideas of Michurin as his own and promoted what he called vernalization, a technique that he claimed would convert winter wheat seeds to spring wheat seeds by simply freezing the seeds. He claimed that his new seeds would dramatically increase wheat yields.

Supported by the Soviet leader Josef Stalin (1879–1953), Lysenko became a powerful Soviet bureaucrat. From 1935 to 1938, he was the scientific director and then the director at the Odessa institute. From 1940 to 1965, Lysenko directed the Institute of Genetics of the Academy of Science of the USSR and served as president of the powerful V. I. Lenin All-Union Academy of Agricultural Sciences. As the effective dictator of Soviet agricultural science, Lysenko wielded his power ruthlessly. Soviet scientists who did not support his ideas found themselves unemployed. Some Soviet scientists who disagreed with Lysenko died from either execution or starvation after being arrested and taken into custody. At one point, at the height of his power, Lysenko claimed that wheat planted in a hostile environment would convert to rye.

Lysenko survived even though widespread adoption of his ideas led to agricultural failures. After Stalin's death in 1953, Lysenko's power declined. In 1964, after changes in the Soviet leadership, Lysenko was finally completely discredited and exiled to a remote agricultural station, though it took even more time for the effects of his regime to fade.

Biology in China since 1945

The state of Chinese biology changed drastically when the Chinese Communist Party (CCP) took over the government in 1949. During the earlier Republican period, many Chinese biologists had studied genetics in the United States under Thomas H. Morgan, first at Columbia and, after 1928, at Caltech. Upon returning to China, most of these biologists established themselves in Yenching University. Meanwhile, a more formal network materialized between the University of Nanking and Cornell University, then the leading institution in plant genetics in the world. The development of both networks was largely assisted by the financial contributions from the Rockefeller Foundation and the China Foundation for the Promotion of Education and Culture.

In early Maoist China, the intellectual patterns of the scientific community were significantly shifted by the new surrounding political forces. The majority of life scientists followed the prevailing policy of the time: “learning from the Soviet Union.” This led to a sharp separation between two groups of Chinese geneticists: the newer generation of Lysenkoists whose influence began to dominate and the older generation of Morganists. Trofim D. Lysenko, a favorite of Josef Stalin, rejected the Mendel-Morganist theoretical framework of the gene in favor of a modified theory, much like the earlier theories of Jean Baptiste Lamarck, which proposed the inheritance of acquired, or learned, traits. Lysenko's neo-Lamarckian doctrine was proclaimed by Stalin and the Central Committee of the Russian Communist Party as a true Marxist biology. Between 1949 and 1956, Russian scientists who visited China also helped promote Lysenko's biological views. In this period, doctrines and teachings associated with Morgan were heavily criticized and forbidden. For example, the famous Republican geneticist Tan Jiazhen, who studied

with Morgan at Caltech in the 1930s under the sponsorship of the Rockefeller Foundation, published no papers between 1950 and 1963.

The Qingdao Symposium of August 1956 in China reopened communications between the Lysenkoists and the Morganists. The symposium was preceded by two important political events in the Soviet Union that greatly altered Lysenko's status in 1955 and 1956. First, Nikita Khrushchev gradually took control of the Soviet Union after Stalin's death. As a result, Stalin was openly criticized at the Twentieth Party Congress in February 1956. Second, by the end of 1955, hundreds of people had signed a petition that requested Lysenko's removal from the presidency of the Lenin Academy of Agricultural Science. Lysenko stepped down in April 1956. These events led to the CCP leaders' critical reevaluation of Lysenkoism and its application in the Chinese context. Mao Zedong's Double-Hundred proposal—"Let a hundred flowers blossom and a hundred schools of thought contend"—enabled the Morganist school of biological thought to be discussed publicly again. Following the Qingdao Symposium, the Morganists gained a firmer footing in China. At Fudan University, for example, Tan Jiazhen was able to establish a Genetics Institute that became the counterforce to the Chinese Academy of Sciences (CAS) Genetics Institute, which was still dominated by the Lysenkoists in the early 1960s.

During the Cultural Revolution (1966–1976), intellectuals were repressed in China to the detriment of science and technology, and both the Lysenkoist and the Morganist groups suffered. By the early 1980s, as the worldwide focus in the life sciences shifted to biotechnology and genetic engineering, a new CAS unit, the Developmental Biology Institute, opened in Beijing in October 1983, followed by the CAS Genetics Engineering Laboratory in 1984. In Shanghai, the institute on genetics research that Tan opened in the early 1960s at Fudan University also metamorphosed into a leading biotechnology unit in the country; meanwhile, other scientists such as Wang Zhiya and Luo Deng were involved in developing the comprehensive Shanghai Center for Biotechnology, another new CAS branch. All of these organizations directly benefited from newly es-

tablished centralized agencies for science policy and funding, such as China's National Natural Science Foundation of China.

The Age of Space and the Rise of Rocketry

Rocket technology dates back to at least 1000 CE in India and Southwest Asia and may well be older. Indian armies used rockets against British invaders in the wars of the late eighteenth century, and the British in turn refined the technology and reintroduced it to Western Europe, where rocketry had been moribund since the Renaissance. Rockets fueled by black powder were pushed to the limits of their capabilities during the next half century and were widely used in Europe for war, signaling, and lifesaving at sea. By the last third of the century, however, rocket makers had exhausted the possibilities of black powder as a fuel, and rocket technology stagnated again. The next major breakthrough—the development of liquid fuels in the 1920s and 1930s—set the stage for a quantum leap in rocket performance and brought outer space (at least theoretically) within reach.

The first serious work on liquid fuel rockets was carried out by Robert H. Goddard, a professor of science at Worcester Polytechnic Institute, in the 1920s. Like his counterparts Konstantin Tsiolkovsky in Russia and Hermann Oberth in Germany, Goddard had analyzed the physics of rocket propulsion and took a particular interest in space travel. Unlike them, Goddard was also a

- 1972—President Richard Nixon announces the space shuttle program.
- 1973 (January)—The USSR abandons its manned lunar landing program.
- 1973 (May)—First flight of the Soyuz-U launch vehicle, still in use as of 2007.
- 1979—First flight of the Ariane launch vehicle.
- 1981—First orbital test flight of the space shuttle.
- 1986—Loss of the space shuttle Challenger.
- 1993—International Space Station proposed; formal U.S.-Russian cooperation in space begins.
- 2003—Loss of the space shuttle Columbia.
- 2004—SpaceShip One becomes the first privately funded vehicle to fly in space.
- 2010 (projected)—Completion of the International Space Station and retirement of the space shuttle.

talented engineer who could translate his theoretical insights into a series of rockets that he built and tested himself. Their published work inspired and guided a new generation of rocket designers, and active rocket societies arose in Germany, the United States, and the Soviet Union during the 1930s. The leaders of those chronically underfunded amateur societies became, during World War II, the leaders of well-funded

military research programs. The most successful of them was Wernher von Braun, a protégé of Oberth, who developed for the Nazis the world's first successful ballistic missile, the V-2.

Both the United States and the Soviet Union had well-developed wartime rocket programs, but both countries built their postwar rocket programs around captured V-2 technology. Both began by experimenting with German V-2s that had been captured intact or assembled from captured parts, then developed their own modifications of the basic V-2 design. Well into the 1950s, the most advanced missiles in the arsenals of both superpowers were straightforward elaborations of von Braun's 1944 design. The two superpowers pursued rocket research in order to enhance their military power—missiles, unlike manned bombers, could not be shot down—but both nations also adapted military missiles to carry out scientific research on the upper atmosphere. Scientific research beyond the atmosphere, in outer space, became possible with the development of intercontinental ballistic missiles in the late 1950s. A missile powerful enough to loft a nuclear warhead halfway across the world, such as the American Atlas or the Soviet R-7, was equally capable of putting a satellite in orbit.

The first satellites, the Soviet Sputnik I launched in November 1957 and the U.S. Explorer I, launched in January 1958, were launched as part of the International Geophysical Year. Others followed in rapid succession, and within four years both superpowers had launched their first manned spacecraft and dispatched their first robot probes to other planets. The rockets used for such launches continued to be adapted from military missiles, but by the early 1960s rocket development had reached a crossroads. The diminishing size and weight of nuclear warheads meant that neither superpower needed missiles more powerful than those already in production. At the same time, however, both superpowers were committing themselves to ambitious manned space programs that did require larger and more powerful launch vehicles. The success of Project Apollo, the American lunar landing program, rested on the success of the Saturn family of launch vehicles that propelled its spacecraft first into Earth's orbit and later to the Moon. The failure of the Soviet lunar landing

was largely due to the premature death of chief designer Sergei Korolev and his successors' inability to produce a reliable heavy-lift booster.

After the race to the moon ended, the Soviet space program fell back on established well-tested designs such as the UR-500 Proton and the R-7 Soyuz. Continually refined and upgraded, these workhorse boosters made hundreds of successful launches and, after the collapse of the Soviet Union in 1991, became the basis of Russia's state-run satellite-launch business. The leaders of the American space program, faced with rapidly shrinking budgets, spent the 1970s developing a partially reusable space shuttle that (they believed) would substantially lower the cost of putting payloads into orbit and ultimately would render traditional single-use launch vehicles obsolete. First flown in April 1981, the shuttle never came close to achieving the high flight rates and low operating costs that its backers had promised. Attempts to make good on those promises led to the Challenger disaster of January 1986, which killed seven astronauts and grounded the program for two and a half years. When the shuttle began flying again in September 1988, it was as a platform for scientific experiments and (as the International Space Station took shape) heavy construction, not as a cargo hauler.

The United States and the USSR had, by the late 1980s, long since ceased to be the world's only space-faring nations. France launched a satellite into Earth's orbit on a booster of its own design in 1965; Japan, China, and Great Britain followed in quick succession in 1970–1971. India, Israel, and Iraq joined the list in the 1980s. The European Space Agency (ESA)—formed jointly by France, Britain, and West Germany in 1975—went on to develop its own family of launch vehicles (the Ariane series, first flown in 1979) and its own program of scientific missions. The ESA also established a commercial arm, Arianespace Corporation, to market its satellite-launching services to other companies and non-space-faring countries. The commercial success of Arianespace helped to lay the groundwork for more recent projects backed entirely by private funds. The most successful of these has been Scaled Composites in Mojave, California, founded by engineer Burt Rutan and backed by computer bil-

lionaire Paul Allen. The company made the world's first privately funded spaceflights in 2004 and formed an alliance with Sir Richard Branson's newly founded space tourism company, Virgin Galactic, the same year.

Manned Spaceflight

The launch of the first Soviet satellite (Sputnik I) in October 1957 and the first American satellite (Explorer I) in January 1958 established outer space as a site for bloodless technological competition between the Cold War superpowers. Sending a human into space was an early goal for both nations. Soviet space planners had discussed the possibility as early as 1956, and the National Advisory Committee on Aeronautics (NACA) had drafted preliminary studies in 1957. The American program introduced its first 7 astronauts with great fanfare in 1959 and began public flight tests of its Mercury spacecraft the same year. The Soviet program, carried out in near-complete secrecy, recruited its first 20 pilots and began flight tests of its one-man Vostok spacecraft in 1960. The first manned Mercury flight was scheduled for January 1961, but safety concerns led National Aeronautics and Space Administration (NASA) to substitute a chimpanzee and postpone the manned flight until May. The delay allowed Yuri Gagarin to become, on April 12, 1961, the first human in space and the first to orbit Earth. NASA successfully launched Alan Shepard on his 15-minute suborbital flight in May 1961 but could not match Gagarin's orbital flight until John Glenn flew in February 1962.

► INTERNATIONAL SPACE STATION

The International Space Station was conceived, in 1993, as a merger of three separate space station projects then in the planning stage: the U.S. Freedom, Russia's Mir 2, and the European Space Agency's Columbus. The Japanese, Canadian, and Brazilian national space agencies also participate in the project. The station consists of a series of interconnected modules that provide living, working, and storage space and are connected to auxiliary elements such as solar arrays, airlocks, and docking ports for visiting spacecraft. Assembly of the station began in November 1998, and the first three-member crew arrived two years later. The station has been continuously occupied ever since, though for three years after the Columbia disaster in January 2003 the crews were reduced from three members to two. It has also played host to four space tourists, each of whom paid \$20 million to the Russian space agency for stays of 7–10 days. The International Space Station was originally envisioned as a platform for scientific research, but budget cuts have eliminated much of its laboratory space, and day-to-day operations have consumed most of its crews' time. It has, to date, proven more significant as a test bed for engineering and construction techniques.

—A. Bowdoin Van Riper

Gagarin's orbital flight continued the series of Soviet space firsts that began with Sputnik. Soviet leaders, eager to present the USSR as the world's premier space-faring nation, called for more of the same, and Soviet space program delivered. Over the next five years it was responsible for the first day-long spaceflight (1961), the first woman in space (1963), the first multi-member crews (1964), the first flight of two spacecraft simultaneously, and the first spacewalk (1965). Doing so, however, pulled resources away from longer-term programs such as plans to land men on the moon. Development problems with the powerful new N-1 booster, the 1966 death of chief designer Sergei Korolev, and the deaths of cosmonauts Vladimir Komarov and Yuri Gagarin (both in 1967) left the program moribund, unable to compete with an American

lunar-landing program that had been gathering momentum steadily since 1961.

Set in motion by President John F. Kennedy's May 1961 call to land a man on the moon "before this decade is out," the American drive for a lunar landing encompassed three distinct manned programs. Project Mercury (1961–1963)—two suborbital and four orbital flights in spacecraft carrying a single pilot—established that humans could not only survive but also perform useful work in space. Project Gemini (1965–1966)—ten orbital flights in two-seat spacecraft—gave NASA experience with space walks, rendezvous and docking maneuvers, and flights up to fourteen days long. Project Apollo (1967–1972) was designed to accomplish the lunar landings themselves. It used three-member crews and a spacecraft consisting of four distinct modules, lifted into orbit by the largest and most powerful rocket ever built, the Saturn V. The first four manned flights, Apollo 7 through Apollo 10, tested the spacecraft in both Earth and lunar orbit. The fifth manned flight, Apollo 11, carried out the first successful landing in July 1969. Five more landings (out of six attempts) followed between November 1969 and December 1972, but political and popular support for the program faded quickly.

Conceived and set in motion at the height of the Cold War, lunar exploration programs were perceived as an expensive anachronism amid the U.S.-Soviet détente of the early 1970s. Three scheduled Apollo missions—18, 19, and 20—were cancelled by the end of 1970, along with a separate series of follow-up missions. The Soviet lunar program, still lacking a visionary leader and a reliable booster, was quietly shut down in 1972. For decades afterward, the Soviet government denied that it had even existed.

After 1972, the two superpowers conspicuously avoided competition in space. Except for a brief experiment with an Earth-orbiting space station (Skylab) in 1973–1974, the United States focused on developing a reusable spacecraft for use in Earth orbit. The space shuttle, which first flew to orbit in April 1981, remained in service for more than 25 years despite unexpectedly high operating costs and accidents that led to the loss of Challenger in 1986 and Columbia in 2003. Except for a brief experiment with a reusable

spacecraft (Buran) in 1988, the Soviet Union focused on building space stations. The seven stations of the Salyut series, operated successively in Earth orbit from April 1971 until February 1991, gave the Soviets valuable experience with the long-term effects of weightlessness. They also laid the engineering groundwork for the larger and more ambitious Mir, the assembly of which began in 1986.

Designed as a three-man research station, Mir was continuously inhabited from 1989 through 1999. Inherited by Russia after the collapse of the Soviet Union in 1991, it played host to astronauts from the former Soviet republics of Ukraine and Kazakhstan as well as from France, Britain, Germany, Austria, Japan, and Canada. The space shuttle orbiter Atlantis docked with Mir on seven missions between June 1995 and October 1997, and the orbiters Discovery and Endeavour each visited the station once in 1998. The visits were part of the Shuttle-Mir program and were complemented by the long-term stays of seven individual American astronauts during the same period. The American visits to Mir ran concurrently with the planning and development of the International Space Station (ISS) and were designed to lay the technological and organizational groundwork that would make construction of the ISS possible.

Assembly of the ISS began in 1998 and is scheduled to be completed in 2010. Plans for its use after that point remain uncertain. The space shuttle, deemed essential to the construction of the station, is scheduled to be retired once the station is completed. Plans for its replacement, dubbed "Apollo on steroids" and designed to support a new program of manned lunar landings, remain sketchy. The most vigorous manned spaceflight programs of the early twenty-first century prove to be those mounted by China (which launched its first piloted spacecraft in October 2003) and space tourism companies such as Virgin Galactic.

Space Probes

Both of the world's major space-faring nations, the United States and the Soviet Union, began launching robot probes in the late 1950s, during the early stages of the space race. Smaller and less complex than spacecraft designed to carry human crews, the probes consumed relatively few resources and could be sent on one-way or high-risk missions with impunity. Collectively, these missions revolutionized scientists' understanding of the solar system, revealing dozens of new moons as well as unsuspected features of planetary surfaces and atmospheres.

The Moon, only a quarter million miles from Earth, was the first target for both Soviet and American probes. Competition between the superpowers was intense, and as they had in Earth-orbiting satellites and would in manned flights, the Soviet Union took an early lead. The USSR's Luna 1 became the first spacecraft to fly past the Moon in January 1959, Luna 2 became (intentionally) the first to impact it in March, and Luna 3 was the first to photograph its far side in October. Making a controlled (or soft) landing on the lunar surface proved more challenging, but after 11 failed attempts Luna 9 achieved this in February 1966. The next probe in the series, Luna 10, became the first spacecraft to enter lunar orbit the following month. After an unpromising start—6 failures in 6 attempts between August 1961 and January 1964—the spacecraft of the U.S. Ranger program achieved 3 successful lunar-impact missions in 1964–1965. These were followed by the 5 successful soft landings (in 7 attempts) of the Surveyor program (1966–1968) and the 5 successful orbital missions (in 5 attempts) of the parallel Lunar Orbiter program (1966–1967).

► MESSAGES TO THE STARS

When Pioneer 10 was launched in 1972, nobody connected with the project was sure that the probe would make it to Jupiter, much less to the edge of the solar system. Hoping that it would survive and eventually reach deep space, scientists connected with the project designed an engraved metal plaque to serve as a greeting to any space-faring alien species that might someday find it. The images on the plaque included a map of the solar system, a diagram showing its position with respect to nearby stars, a schematic diagram of the spacecraft, and line drawings of a nude man and woman. The goal of the images was to communicate a simple message: “We made this machine. This is where we live, and what we look like.”

Pioneer 11 carried an identical plaque, but Voyager 1 and 2, launched in the mid-1970s and also designed to leave the solar system after flybys of the outer planets, carried more elaborate messages. Each bore a 12-inch gold-plated copper disk that carried not only symbols but also 115 images of Earth and a variety of audio clips. The record, designed on the same principle as a phonograph record, was packed inside an aluminum box along with the pictorial instructions and key components needed to build a machine to play it. The sounds encoded on it included wind, running water, animal noises, snippets of music from cultures throughout the world, and greetings in 55 human languages.

—A. Bowdoin Van Riper

Attempts to send probes to the inner planets—Venus, Mars, and to a lesser extent Mercury—also began in the early 1960s. The American Mariner 2 carried out the first flyby of Venus in 1962, but further exploration lagged behind programs aimed at the Moon and Mars. The Soviet space program, meanwhile, made a specialty of Venus. Probes from its Venera series executed the first crash-landing on its surface (1965), returned the first data from inside its atmosphere (1966), and made the first soft landing (1970). The scientific investigation of Mars hit its stride in the late 1960s and early 1970s. The Mariner 6 and Mariner 7 flyby missions returned the first high-resolution photographs of the Martian sur-

face in 1969, and the Mariner 9 orbiter (along with the Soviet Mars 2 and Mars 3 missions) expanded photographic coverage in 1970–1971. The Mars 3 mission also deployed a lander that, though it landed safely, ceased transmissions less than a minute later.

The years 1970–1971 marked a watershed in the history of planetary exploration. They marked the end of the Soviet-American space race and the competition for firsts that had gone with it. They also marked the abandonment by both nations of any long-term plans for manned flights beyond Earth’s orbit. Planetary exploration was, from 1970–1971 onward, entirely the province of increasingly sophisticated robot probes aimed at an increasingly wide range of destinations.

The second phase of robotic exploration, which began in 1970–1971, lasted until the collapse of the Soviet Union in 1990–1991. It included the first flybys of Mercury (by Mariner 10 in 1973), Jupiter (by Pioneer 10 the same year), and Saturn (by Pioneer 11 in 1979); the first successful soft landings on Mars (Viking 1 and Viking 2 in 1976); missions to Halley’s Comet in 1985–1986; and the mapping of the surface of Venus by radar (Venera 15 and Venera 16 in 1983–1984 and Magellan in 1990–1994). The technology used in robot probes also grew more diverse. Luna 16 returned samples from the Moon in 1970, while Luna 18 and Luna 21 deployed robotic rovers on the lunar surface in 1970 and 1973. Venera 13 returned the first color images from the surface of Venus in 1981, and the Soviet Vega missions of 1985 deployed balloons in the Venusian atmosphere to measure wind speed and direction at high altitudes. The undisputed climax of the second phase, however, was Voyager 2’s grand tour of the outer solar system. Built and run by NASA’s Jet Propulsion Laboratory, Voyager 2 passed Jupiter in 1979 and used the giant planet’s gravity as a slingshot to accelerate it toward Saturn. The gravitational pull of Saturn, combined with carefully timed bursts of energy from its thrusters, sent it on to rendezvous with Uranus (1986) and Neptune (1989). It thus became the first spacecraft to survey the two outermost planets, the only spacecraft to fly by four different worlds, and the most scientifically productive space probe in history.

The space probes of the 1970s and 1980s tended to be large, complex machines designed from scratch for specific missions. This made them extremely capable but also costly (in time and resources) to build. The third phase of robotic exploration, which began in the mid-1990s, was marked by a partial shift toward smaller, simpler probes that could be built relatively quickly and cheaply and thus launched more frequently. This approach—summed up in NASA's mid-1990s slogan “faster, better, cheaper”—achieved an early success with the Mars Pathfinder mission of 1997, which drew worldwide attention for its small six-wheeled rover, Sojourner. It also produced Lunar Prospector, the first American probe of the Moon since the Lunar Orbiter program 30 years earlier, and the comet-investigation spacecraft Deep Impact and Stardust. NASA's flagship missions continued, however, to use large and elaborate spacecraft. Galileo made an extensive survey of Jupiter in 1995–2003 and dropped the first probe into its atmosphere. The twin Mars Exploration Rover missions deployed a pair of large sophisticated rovers named Spirit and Opportunity on opposite sides of Mars during 2004. The Cassini-Huygens mission—the most elaborate to date—put Cassini into orbit around Saturn in late 2004 and dispatched Huygens to a soft landing on the surface of Saturn's largest moon, Titan, in early 2005. New Horizons, a spacecraft intermediate in size between flagship probes such as Cassini-Huygens and smaller vehicles such as Mars Pathfinder, is expected to fly past Pluto in 2015 and then investigate the icy minor planets of the Kuiper Belt beyond.

The Hubble Space Telescope and Science in Space

The history of scientific research in space begins with the first American artificial satellite, Explorer 1, that discovered that Earth is encircled by belts of radiation. It includes robot probes and landers sent to other planets, satellites designed to monitor conditions on Earth, and experiments carried out by astronauts aboard the space shuttle and on the surface of the Moon. The most powerful tools yet used for space science, however, are the four Great Observatories launched by the National Aeronautics and Space Administration (NASA) between 1990 and 2003. Each of the four observatories, named after a great twentieth-century astronomer or physicist, was designed to monitor a specific part of the

Illustration of the Hubble space telescope in orbit, first launched in 1990. (European Space Agency)

➤ SEARCH FOR EXTRATERRESTRIAL INTELLIGENCE

Search for Extraterrestrial Intelligence (SETI) was never a specific space communications program but rather a series of attempts to receive messages from extraterrestrials. The impetus for SETI arose in the 1950s when Nobel laureate Enrico Fermi argued that given the size and age of the universe, it was probable that extraterrestrial life existed and must be detectable in some way. Scientists concluded that the best evidence for life would come from radio waves. In 1960, Cornell professor Frank Drake performed the first modern SETI experiment, named Project Ozma, with a small radio telescope. Other universities, often in conjunction with the National Aeronautics and Space Administration (NASA), also developed radio telescopes to search the sky for transmissions. The most famous event in SETI research occurred in 1977 when an especially strong signal was received at Ohio State University. This was dubbed the Wow! signal because of the notes in the margin. When NASA briefly stopped funding SETI research in 1993 (funding resumed in 2003), a private organization called the SETI Institute was founded in Mountain View, California, by Frank Drake, Carl Sagan, and other proponents of SETI. The SETI Institute enlisted the help of millions of people who downloaded a screensaver on their home computers to help analyze collected data. The NASA Pioneer and Voyager Probes on their extended missions have carried a selection of images, greetings, and sounds in case they are recovered by extraterrestrials.

electromagnetic spectrum. Together, the four cover the entire spectrum and enable scientists to view objects of interest from multiple perspectives.

Three of the Great Observatories are well known only to astronomers. The Compton Gamma Ray Observatory, in orbit from April 1991 to June 2000, carried instruments capable of monitoring long-wavelength gamma radiation from black holes, quasars, pulsars, and other energy sources. The Chandra X-Ray Observatory, launched in July 1999, monitors X-ray emissions from sources up to billions of light years away. The Spitzer Telescope, launched in 2003, sees in the thermal infrared region of the spectrum and

can look into the hearts of galaxies. It is ideally suited to observing molecular clouds, small and dim stars invisible to ordinary telescopes, and the nurseries where new stars are being born.

The most famous of the Great Observatories, however, was the first to be launched: the Hubble Space Telescope, named after the astronomer (Edwin Hubble, 1889–1953) who first established that the universe was expanding. Carried to orbit aboard the space shuttle *Discovery* in 1990, the Hubble is a reflecting (mirror-based as opposed to lens-based) telescope capable of observing not only the visible light portions of the electromagnetic spectrum but also the adjacent near-infrared and ultraviolet sections. Orbiting above Earth's atmosphere, which absorbs ultraviolet light and scatters visible light, its ability to capture images of unprecedented clarity and depth has made it both a powerful tool for astronomers and a public relations triumph for NASA. Hubble has recorded the collision of comet Shoemaker-Levy 9 with Jupiter, the birth and death of stars, and the existence of auroras in the atmospheres of Jupiter and Saturn. Images from Hubble have also helped to confirm the existence of black holes, clarify the nature of quasars, and (fittingly) shed light on the dark energy that drives the expansion of the universe.

Hubble is the only one of the Great Observatories capable of being serviced and upgraded by astronauts while in orbit. This capability proved critical when, soon after it was activated, Hubble was discovered to have a small but critical flaw in the shape of its main mirror that reduced the clarity of the images it could capture. On the first Hubble servicing mission, flown in December 1993, a team led by veteran astronaut Story Musgrave installed a specially designed package of electronics and corrective mirrors that all but eliminated the problem. Subsequent servicing missions in February 1997, December 1999, and March 2002 further expanded the Hubble's capabilities and extended its useful life. After the loss of the shuttle *Columbia* in 2003, NASA administrator Sean O'Keefe announced that no further manned servicing missions would be flown. The decision, which drew a storm of protests from space scientists and members of the public, was formally reversed by NASA administrator Michael Griffin in October

2006. During the final Hubble service mission in May 2009, astronauts made numerous spacewalks to repair and replace Hubble components in order to keep the telescope functioning until 2013, by which time its replacement is scheduled to be operational.

Cyclotrons

One of the earliest types of particle accelerators, cyclotrons, has contributed to the development of nuclear physics and nuclear medicine. The first cyclotron, conceived by physicist Ernest O. Lawrence, went into operation in 1934 at the University of California, Berkeley. Lawrence received the Nobel Prize for Physics in 1939 for his development of the cyclotron. During World War II, the U.S. Manhattan Project used cyclotrons to enrich uranium for atomic bombs. After 1945, universities and research laboratories worldwide acquired cyclotrons either through their own efforts or via commercial purchases for research on subatomic particles.

The significant investment in postwar nuclear physics research created a demand for scientific instruments. The cyclotron, which accelerates particles in a closed loop, was a preferred alternative to other particle accelerators due to its relative low cost and the advantages of its compact design. Linear accelerators move particles in a straight line, and because it was not then possible to generate radio waves with both high power and high frequency, contemporary linear accelerators required multiple stages to offset the low power at each stage. Since cyclotrons accelerate particles in a circular path, in a given area of surface space occupied by the device a cyclotron contains more distance for a particle to travel than does a linear accelerator, and by design a cyclotron inherently provides more opportunities to accelerate the particles. For these

INTERNATIONAL ATOMIC ENERGY AGENCY

The International Atomic Energy Agency (IAEA) was founded as an autonomous department under the United Nations in 1957. Based in Vienna, Austria, its original purpose was to ensure the peaceful use of nuclear energy. After the Three Mile Island (1979) and Chernobyl (1986) disasters, the IAEA was given an expanded purview to provide inspections to ensure that nuclear facilities were being run safely. After the 1968 Nonproliferation Treaty, the IAEA became more concerned about halting the spread of nuclear material for military uses. The IAEA collaborates with other agencies, notably in the field of medicine, if radiation is involved. The IAEA has come under criticism in the last couple of decades for failing to keep closer scrutiny over Iraq, North Korea, and some of the former republics of the Soviet Union. The IAEA is often bound by the will of host nations, and its budget is fairly small for its newly expanded duties.

reasons, cyclotrons were less expensive to construct and more feasible than linear particle accelerators for new and growing institutions. Nevertheless, linear accelerators can produce particle energies that exceed those possible with cyclotrons and are also capable of producing a nearly continuous stream of particles, unlike a cyclotron's limited ability to only periodically raise a particle's energy level.

The Riken Institute for Physical and Chemical Research in Tokyo began running the first working cyclotron outside of the United States in 1937. By 1946, more than 20 cyclotrons were in operation in the United States, and 8 were in operation in other countries. Cyclotrons totaled 72 worldwide in 1969, and this number had doubled again by 1986. By 1998 more than 200 cyclotrons were in operation globally. By 2004, a cyclotron was in operation on every continent except Antarctica, with more than 25 percent of these located in research laboratories and universities in Asia.

In addition to furthering research into nuclear physics, scientists successfully adapted cyclotrons for medical use. The U.S. National Cancer

Institute funded research into the modification of cyclotrons in 1971, with patient treatments initiated in 1984. Doctors employed medical, or clinical, cyclotrons by adjusting the frequency of the X-rays produced by a cyclotron's radiation. So modified, a cyclotron's radiation can penetrate a limited distance and kill tumors in the human body in a process called external beam radiotherapy. In addition to direct treatment of patients, scientists developed cyclotrons that produce radioisotopes used in nuclear medicine, radiation therapy, and medical research. Radioisotopes produced by cyclotrons were used in positron emission tomography (PET) and computed tomography (CT) machines for radiotherapy.

Nuclear Reactors

Nuclear reactors are devices that create, sustain, and control a chain of nuclear fission reactions. Enrico Fermi and Leo Szilard demonstrated the first controlled chain reaction at the University of Chicago on December 2, 1942, but it was not until after World War II that governments and the electric power industry seriously pursued the development of commercial nuclear reactors. Although corporations based in the United States dominated the global nuclear industry from the 1960s through the 1970s, state-subsidized programs in other nations also contributed to the development of nuclear reactors.

In a commercial nuclear reactor, the heat from nuclear chain reactions creates steam, which in turn is used to generate electricity. In most reactors, this nuclear chain reaction occurs

when neutrons bombard uranium atoms, which split (through nuclear fission) to release energy and additional neutrons, thereby bombarding neighboring atoms and continuing the reaction. The high speed of a neutron limits its ability to completely consume uranium fuel, and a neutron moderator can reduce the speed of neutrons and increase the extent to which the fuel is consumed. The extreme temperatures created by this process require the use of a cooling material, which dramatically affects the design of the nuclear reactor.

Two basic types of nuclear reactors characterized the postwar world: fast neutron reactors and thermal (slow) reactors. Less common were the fast reactors in which the nuclear chain reaction is sustained by high-energy fast neutrons. Such a reactor has no neutron moderator, is typically cooled by liquid metal because of the high temperatures it generates, and uses fuel such as highly enriched uranium or plutonium in order to provide enough fuel for the fast neutrons. In 1946 scientists at Los Alamos, New Mexico, built CLEMENTINE, the first fast reactor, which used plutonium metal fuel and mercury coolant. The United Kingdom's fast reactor program at Dounreay, Scotland (1957 to 1994), used NaK (78 percent potassium and 22 percent sodium) and sodium-cooled reactors. By 1985 France, Germany, India, Japan, and the Soviet Union also operated fast reactors.

More common among nuclear power plants were thermal reactors, which use slower low-energy thermal neutrons, have moderators to slow the neutrons, do not require liquid metal as a coolant, and use nonenriched nuclear fuel because of the ability of slow neutrons to more efficiently consume uranium. There were four significant versions. By far the most prevalent was the light-water or pressurized water reactor (LWR or PWR), which used ordinary light water as both coolant and moderator. Less widespread was the boiling water reactor (BWR), which likewise used light water but generated the steam for power production within the reactor itself instead of using heat exchangers. Unlike the LWR and PWR reactors, the CANDU reactor used pressurized heavy water (deuterium oxide) as a moderator. A Canadian public-private consortium designed CANDU in the late 1950s and 1960s,

and many nations installed and operated reactors of this type. Finally, the Soviet Union developed RBMK reactors, which used light water for cooling, graphite for moderation, and natural uranium for fuel. Scientists generally considered these reactors unstable. The Soviet Union had ceased new construction prior to the 1986 explosion of an RBMK reactor in Chernobyl, Ukraine, the worst civilian nuclear accident to date and caused by human errors.

Nuclear reactors in operation in the late 1990s were generally considered second- or third-generation systems that had superseded the first-generation prototypes constructed in the 1950s and 1960s. In May 2001, 11 nations formed the Generation IV International Forum to promote

Cooling towers at a nuclear power station in Dukovany, Czech Republic. (Shutterstock)

➤ NO NUKES PROTESTS

Beginning in the late 1970s, many people all over the world protested against the construction of nuclear power plants based on the belief that nuclear power plants were inherently unsafe and contributed to the environmental degradation of the earth. These movements also were closely connected to the antinuclear weapons movement of these decades, with many of the same people participating in both movements and identifying themselves as antinuclear in regard to both weaponry and energy issues. While some people opposed nuclear plants being built locally in their communities, many others opposed their construction anywhere. The antinuclear power movement has been among the most broadly based and widely supported environmental movements in history.

Accidents at nuclear power plants increased public opposition to the use of nuclear power as an energy source. In 1978 there were 222 nuclear power reactors operating worldwide, with 71 of them in the United States providing 12 percent of the total electricity produced nationally. After the partial meltdown at Three Mile Island in Harrisburg, Pennsylvania, in March 1979, worldwide protests against nuclear power increased dramatically along with mistrust of government and industrial officials who insisted on the safety of nuclear power. In August 1979 more than 200,000 people participated in a protest in New York City opposing nuclear power, the largest antinuke protest in U.S.

history and only one of dozens held that day around the country. Before 1977 there were more protests against nuclear weapons than against nuclear power. This reversed in 1978, and for a period of four years there were more protests against nuclear power plants. In 1981 more than 1,000 protestors were arrested at the still under construction Diablo Canyon nuclear power plant outside of San Luis Obispo, California.

In 1986 one of the reactors at the Chernobyl plant located in the Soviet Ukraine suffered a major meltdown, releasing large amounts of radiation into the atmosphere over Eastern and Northern Europe. This accident sparked international outrage and virtually ended public support of nuclear power. It is a historical irony that many of the same people who protested nuclear power in the past now champion its use as a means of addressing global warming.

the research and development of new nuclear reactors based on the technology goals of improved nuclear safety, improved proliferation resistance, minimized waste and natural resource utilization, and decreased construction and operation costs.

Access to technology for the peaceful use of nuclear reactors is guaranteed to signatories of the Nuclear Non-Proliferation Treaty (NPT), which went into effect in 1970. The NPT is generally considered a bargain for nations without nuclear weapons. According to the NPT, non-nuclear weapons states (the significant majority) refrain from developing nuclear weapons in exchange for the right to develop, purchase, and sell nuclear technology for peaceful use. In theory, nations that want nuclear reactors face no legal restrictions. In practice, distinguishing peaceful nuclear technology proved to be a difficult and highly politicized process.

Nuclear Waste Disposal

The safe and permanent disposal of nuclear waste did not become a significant public policy issue until nuclear power plants had been in operation for several years. The medical and environmental harm caused by radioactive nuclear waste was neither apparent to the public nor advertised by the global nuclear industry in the early years of nuclear reactor construction in the 1950s and early 1960s. However, a rising awareness of the impact of nuclear pollution combined with a general increase in environmental awareness and activism in the early 1970s made nuclear waste disposal a growing political problem. At the same time, an increased number of nuclear power plants quantitatively increased the amount of nuclear waste requiring permanent disposal. By 2006 many observers believed that the problem

of nuclear waste disposal was one that required resolution in order to avoid an environmental crisis.

Regulatory agencies and the nuclear industry have classified nuclear waste into three categories: low, intermediate, and high. Medical and industrial use of radioactive isotopes creates low-level waste such as paper, tools, clothing, and so on that contains small amounts of short-lived radioactive material. This waste does not require shielding during handling and transport and usually has been compacted or incinerated prior to land burial. By contrast, intermediate-level waste includes higher amounts of radioactivity that require some shielding. It typically consists of contaminated resins, metals, and other materials. Intermediate-level waste typically has been solidified in concrete or bitumen for disposal.

High-level waste consists of the fission products generated in the core of a nuclear reactor and is high in both radioactivity and temperature. When nuclear reactors first began to generate waste in the 1950s and 1960s, scientists and engineers developed a two-stage process of waste storage. First, power plants stored the spent nuclear fuel in pools of water, which impeded any continuing nuclear chain reactions and cooled the extremely hot material. Second, after a period of wet storage, the material was moved to dry storage facilities in steel and concrete containers. No centralized global plan or facility for nuclear waste disposal currently exists, and dry storage typically has been arranged on or near the same site as the nuclear reactor.

Beginning in the 1970s, many governments began to actively seek long-term disposal options for high-level nuclear waste, and the concept of a deep geological disposal received the backing of science and industry. However, the idea of moving high-level waste from aboveground dry storage to geologically stable underground vaults was politically untenable, and public protests thwarted many plans for underground storage of nuclear waste. For example, in 1970 the U.S. Atomic Energy Commission announced plans to construct a repository near Lyons, Kansas. Unexpected external opposition to the plan and strong challenges from regional politicians forced the proposal's withdrawal. Since then, Belgium, Canada, Finland, France, Germany, Sweden, Swit-

A facility in Sweden for storing nuclear waste, located on the Swedish coast near the Forsmark reactor complex. (Karen Kasmauski/Corbis)

zerland, the United Kingdom, and the United States have all performed detailed studies involving exploratory boreholes, shafts, and ramps in underground research laboratories. Most notably and with much continuing controversy, the U.S. Department of Energy designated Yucca Mountain in Nevada as the future site of a terminal storage facility for spent nuclear reactor fuel and other radioactive waste. However, as of 2009 no permanent underground or undersea facilities for nuclear waste disposal existed or were under construction anywhere in the world.

Nuclear Plant Disasters

On September 29, 1957, at 16:20 local time, a chemical explosion at the nuclear fuel reprocessing facility in Mayak, the Southern Urals, Russia, then part of the Soviet Union, caused the release of 74×10^{16} becquerel (Bq; 1 curie is

37 billion Bq) of fission products, of which 10 percent became dispersed into the atmosphere. The accident became known as the Kyshtym disaster, taking its name from the closest populated town rather than from the plant itself. The disaster was reported internationally only in 1976, when Dr. Zhores Medvedev, a dissident scientist from the former USSR, communicated the accident in England, and the Soviet Union acknowledged the accident only in 1989. The radioactive emissions spread over a region of 3,861–7,722 square miles (10,000–20,000 square kilometers) known as the Eastern Ural Radioactive Trace (EURT), which later became a study area for the ecological effects of radiation. It is estimated that the intensity of radiation released from this accident was double that later released at Chernobyl.

Several radioactive emission events were, in fact, associated with the Mayak nuclear facility. The plant started polluting the environment during its first decade of operation, between 1949 and 1956, when approximately 20 billion gallons (76 million cubic meters) of liquid radioactive waste leaked into the Techa River. Hence, the Kyshtym nuclear disaster is considered to be the second environmental tragedy associated with this facility. In addition, some of the radioactive waste from the facility was diverted into the nearby Karachay Lake, and during the hot summer of 1967, dust from the lake bed spread over a large area, covering numerous villages inhabited by over 40,000 people. This was reported as the most polluted place on the planet, and spending a few minutes at this site was predicted to be sufficient to receive lethal radioactivity doses. In recent years, efforts to contain the radioactivity were made by filling the lake with blocks of concrete.

The same year as the Kyshtym disaster, 1957, brought Great Britain's largest nuclear disaster. Between October 10 and 11, a fire at number 1 Pile at the Windscale nuclear complex released approximately 1.86×10^{16} Bq radioactivity into the surrounding area. The radioactivity cloud subsequently dispersed, and isotopes could be detected over England, Wales, and parts of Northern Europe. A governmental inquiry was initiated within days, and the incident was widely reported in the media; this represented,

➤ RANKING NUCLEAR DISASTERS

Over 400 nuclear power plants that use nuclear fission technology for energy production exist worldwide, and establishing safe control systems for these facilities represents one of the major challenges for the twenty-first century. The International Nuclear Event Scale (INES), established to communicate to the public the significance of nuclear and radiological events, lists seven levels with which to rank accidents: 1, anomaly; 2, incident; 3, serious incident; 4, accident with local consequences; 5, accident with wider consequences; 6, serious accident; and 7, major accident. Each level describes an accident ten times more severe than that of the preceding level. Based on this scale, Three Mile Island and Windscale are classified as level 5, Kyshtym as level 6, and the Chernobyl explosion as level 7.

—Richard Stein

in fact, the first major publicized instance of radioactivity.

Both the Kyshtym and the Windscale accidents occurred at installations whose main purpose was to produce plutonium for national weapons programs. While the Windscale accident did not have any reported ecological effects, substantial ecological damage was observed in most areas contaminated by the Kyshtym accident.

On April 26, 1986, two violent explosions destroyed the core of Unit 4 of the power plant and roof of the Chernobyl nuclear power plant in Pripyat, Ukraine, in what is considered the worst nuclear accident in history. The accident generated a massive radioactivity cloud above most of Europe, particularly Ukraine, Belarus, and western Russia. An estimated 1.85×10^{18} Bq of total radioactivity were released, polluting approximately 49 million acres (200,000 square kilometers) of land. The nuclear disaster damaged the ecosystem to such an extent that even ten years after the accident, the radioactive contamination was still directly affecting the development of trees. Many studies that examined a link to various diseases were inconclusive. The main well-established medical impact was an increase in the rates of childhood thyroid can-

cer. While the rate of thyroid cancer in children under 15 years old was, prior to the accident, around 0.3–0.5 per million, during the 1991–1994 period it increased to over 30 per million in Belarus and to over 90 per million in the Gomel region, situated immediately north of Chernobyl.

The most significant nuclear accident in the history of the U.S. commercial nuclear power industry occurred on March 28, 1979, at the Three Mile Island nuclear power plant near Harrisburg, Pennsylvania. This accident occurred as a result of a partial core meltdown in Unit 2, a pressurized water reactor and, as a result, 0.5×10^{12} Bq of radiation were released into the environment. This accident caused minimal population exposure. It was estimated that approximately 2 million people in the area were exposed to about 1 millirem of radiation. For comparison, an X-ray causes an exposure of approximately 6 millirems. Many studies were unable to conclude whether the accident had any health-related effects. Improved plant design, enhanced operator training, and expanded safety inspections at nuclear power plants are a few of the safety measures implemented in the wake of this accident.

The Pursuit of Fusion Power

The process of nuclear fusion combines atoms rather than splitting them apart as nuclear fission does. The German-born physicist Hans Bethe (1906–2005), who fled the Nazis to America, proposed in 1938, in a claim that has since been validated, that the process of fusion powered the Sun. A claim in 1951 by the Argentine president Juan Perón (1895–1974) that his country had built a fusion reactor astonished the world and turned out to be false. In the early 1950s, American scientists began to develop a way to use

magnetic fields to confine the high-temperature plasma necessary for fusion to occur in order to put the power source of the Sun into a magnetic bottle. The U.S. Atomic Energy Commission sponsored the secret work. The United States dropped the shroud of secrecy around the fusion effort after the Soviet success with Sputnik I in 1957 as part of a publicity effort to show that the United States still engaged in groundbreaking scientific research, though the effort eventually foundered on technical difficulties.

American scientists revived their fusion research effort in the early 1970s as the nuclear

► COLD FUSION

On March 23, 1989, the chemists Stanley Pons (1943–) and Martin Fleischmann (1927–) held a press conference with officials at the University of Utah, where they announced that a simple laboratory experiment had created excess heat that could only be explained by a process of fusion occurring at room temperatures (thus the term “cold fusion”). Fleischmann was a respected senior electrochemist from England and a fellow of the Royal Society. Normally, the results of such an experiment would be presented at a scientific meeting or published in a scientific journal. Pons, Fleischmann, and university officials chose such an unorthodox method because another scientist, the physicist Steven E. Jones (1949–) at nearby Brigham Young University, was also engaged in similar research. Whoever claimed priority on such a breakthrough technology stood to earn billions of dollars from a source of energy that promised to be environmentally friendly and cheap.

The experiment of Pons and Fleischmann consisted of a tabletop apparatus in which deuterium was electrolyzed by two electrodes made of palladium and platinum. The experiment appeared to generate more energy than was put into it. From the beginning, many scientists, especially physicists, doubted that such a simple experiment could yield such dramatic results. Other laboratories around the world attempted to duplicate the experiment; some met with partial success, while many failed. A laboratory in Italy announced that it had detected excess neutrons in its experiment,

an indication of fusion. The media went into a frenzy, and governments quickly announced funding for cold fusion research.

In a meeting of the American Physical Society in Baltimore on May 1, 1989, physicists condemned the entire idea of cold fusion. From a sociological standpoint, Pons and Fleischmann had three strikes against them. They were chemists claiming to succeed where generations of physicists working on hot fusion had failed, they had not followed the normal process of scientific publication, and their simple experiment proved not to be simple to reproduce. Cold fusion became a classic cautionary tale teaching the importance of repeating experimental results enough times to be certain and of following the accepted procedures of publication.

The story did not end there. Pons and Fleischmann left Utah for Nice, France, where the Japanese corporation Toyota funded their research. At the same time, scientists at the U.S. Office of Naval Research conducted over 200 experiments in cold fusion during the 1990s, achieving inconsistent results. They did find hints that the composition of trace elements in the palladium electrode was very important and that microscopic cracks stopped the experiment from producing excess energy. When they published their results, their work was ignored. As of 2009, research on cold fusion has become pariah science, conducted on the fringes of respectable science.

—Eric G. Swedin

industry came under concerted assault by the new environmental movement. Fusion enthusiasts expected a commercial fusion reactor to be safer and generate less radioactive waste than fission reactors. The radioactive waste generated by fusion reactors would also have a much shorter half-life than the radioactive waste of fission reactors. The 1970s' effort continued into the 1980s before funding fizzled and the U.S. Department of Energy elected to begin to work with other countries on the problem, spreading the cost of research. The Soviets, Japanese, French, and other European countries had already worked on fusion, with the Soviet tokamak method of confinement becoming a favored approach even in the United States. Despite bil-

lions of dollars in research, the promise of fusion remains only a hope for cheaper, cleaner electricity. At the end of the century, fusion researchers organized an international consortium, ITER (from the Latin term *iter*, meaning "the way"), to build a large research fusion reactor in Cadarache, France. The site is expected to be operational in 2016.

■ Introduction: Medicine and Health Care

Medical procedures and pharmaceuticals underwent rapid advances during both world wars. The ability of government bureaucracies to organize medical facilities as part of war mobilization contributed to sweeping changes in the post-1945 world in terms of medicine and health care. Initiatives in the United States, most notably the National Institutes of Health, created in 1948, illustrate the postwar government support for the research and development of treatments, pharmaceuticals, and state-of-the-art medical equipment. The establishment of Britain's National Health Service (NHS) in 1948 provided a model for state-funded universal health care as it transformed hospitals, clinics, and physicians into state institutions and employees. New international organizations such as the United Nations (UN) and the World Health Organization (WHO) also increased attention to the health needs of the developing world. International efforts to eradicate malaria, smallpox, and polio succeeded in eliminating these diseases from large swaths of postcolonial Asia and Africa, inadvertently triggering exponential population growth.

Advances in medical procedures, pharmaceuticals, and technology drastically accelerated

during the late twentieth and early twenty-first centuries as medicine became an increasingly transnational business venture with tremendous profit potential. Multinational pharmaceutical corporations, mostly centered in the West, developed new treatments and products to curtail disease and treat medical conditions. While such developments were advantageous to those who could afford it, polemic public debates across the West, particularly in the United States, emerged as health care became increasingly expensive and government funding provisions became inadequate to meet the needs of large portions of its population. The elderly and the poor were increasingly vulnerable to poor health as a result of the scaling down of the welfare state that occurred in the late 1970s and early 1980s in parts of the West. At the same time, various parts of the developing world struggled with pandemics such as HIV/AIDS, not to mention diseases related to malnutrition given the growing economic disparity vis-à-vis the developed world. Structural economic adjustments within multiple Latin American and sub-Saharan African states to meet obligations to the World Bank and the International Monetary Fund also led to severe cuts to existing health care systems. In the same period,

as of 1977, in a major shift in policy and philosophy, the WHO gave new support to indigenous medical practices, arguing that traditional remedies and treatments could be of great value to populations in countries such as India, Tibet, China, and Africa, as an adjunct to the more expensive Western model.

As populations expand and age, medical developments and health care will continue to be important and often contentious issues at the national and international levels.

—*Abraham O. Mendoza*

Globalization of Medical Science

Following World War II, advances in surgery, pharmaceuticals, medical education, and public health measures ensured the steady globalization of medical science. In the surgical field, improvements in anesthetic techniques, specialist teams, and organ transplantation saved countless lives. Pharmaceutical science provided new weapons for the fight against devastating and frequently fatal diseases. Reforms in medical education extended an army of specialists and highly trained professionals around the world. And public health measures helped prevent the spread of infectious diseases that previously decimated populations. While the original pattern for the globalization of medicine involved the imposition of Western standards and techniques on the developing world, in recent decades groups including the World Health Organization (WHO), created in 1948 as an intergovernmental arm of the United Nations, have begun to place greater emphasis on traditional medical practices.

Philanthropic organizations such as the Rockefeller Foundation played a major role in spreading the contributions of Western medical science in the first half of the twentieth century. After the war, philanthropists were joined by private pharmaceutical corporations that targeted non-Western markets and new international medical organizations that extended the knowledge, techniques, and the professional practice of Western medical science.

The WHO played a major role in the globalization of medical science in the second half of the twentieth century. Intent on fighting a war against disease, WHO medical professionals and

scientists insisted that international progress in health depended on bringing Western scientific medicine to the world. In its first year of existence, the WHO sent teams of medical officers, nurses, sanitary engineers, public health officers, bacteriologists, and other personnel to China, Ethiopia, Haiti, India, Ceylon, North Korea, South Korea, and the Philippines. By the early twenty-first century, the WHO included more than 190 member nations.

The first major WHO international campaign was fought against malaria. Despite an initial goal of total victory over the disease, by the mid-1960s the WHO scaled back funding amid criticism that the program had failed. While a variety of immunization campaigns subsequently made great strides against measles, diphtheria, whooping cough, tetanus, tuberculosis, and polio, the only successful eradication campaign came with smallpox in 1979.

Amid a worldwide economic recession and the heightening of Cold War tensions, WHO and UNICEF members convened in 1978 at an international conference in Alma-Ata, Kazakhstan, to discuss the globalization of medical science. The Alma-Ata Declaration emerged as a major milestone of the twentieth century in the field of public health and medicine. It identified the new concept of primary health care as the key to the attainment of the WHO goal of “Health for All by the Year 2000.” The Alma-Ata Declaration affirmed health as a fundamental human right and called for a transformation of conventional health care systems by encouraging collaboration between medical scientists and traditional healers through community organizing around the world.

In the closing decades of the twentieth century, many more countries questioned the ability of Western medical science to meet the basic health needs of all people. Subsequently, the WHO fundamentally changed its relationship with the developing world by promoting the study and preservation of indigenous folk medical knowledge. This reorientation of medical science was also accompanied by a growing body of literature in medical anthropology and the sociology of knowledge that often portrayed scientific medicine as an agent of colonization and imperial expansion.

➤ TRADITIONAL TIBETAN MEDICINE AND MODERNIZATION

Following the Chinese communist invasion of 1951, Tibetan society was propelled into a new era. In 1959, the 14th Dalai Lama, Tenzin Gyatso, together with thousands of Tibetans, escaped from Tibet to India, bringing with them their unique cultural and religious heritage. One of the first Tibetan institutions to be reestablished in exile was the Mentseekhang, or the Tibetan Medicine and Astrology Institute, originally a Tibetan hospital and college in Lhasa founded in 1916. Although it was not the first time that Tibetan medicine had come to a foreign land, it marked the beginning of substantial changes to its practice.

After the destruction of the traditional social system in Tibet and much of the country's religious and cultural heritage both prior to and during the Cultural Revolution (1966–1976), Tibetan medicine experienced a slow revival. The Chinese government started to support it as a member of the family of Chinese medicines, and it was partially integrated into the official health care system after many of its aspects were standardized, modernized, and cleansed of religious ideas.

With the integration of China into the global market economy from the 1990s, Tibetan medicines became increasingly manufactured in large pharmaceutical factories and geared toward urban Tibetans, Chinese, and the export market. This led to new priorities in production, particularly compliance with the “Good Manufacturing Practices” (GMP) based on documents issued by the World Health Organization (WHO). GMP originally regulated the production and packaging of biomedical drugs. However, it is now applied to many traditional medicines gaining global distribution. In the case of Tibetan medicine, some of GMP's standards contradict and compromise those laid out in indigenous texts.

In the fundamental Tibetan medical work the *Gyu Shi*, a seven-limb procedure for identifying,

Advertisement for Cheezheng “Tibetan medical” pain relieving plasters, Lhasa, 2003. (Theresia Hofer)

collecting, cultivating, and processing plant, mineral, and animal ingredients, is described. In this, the collection of certain plants is linked to the cycle of the moon, and the harvester is instructed to collect with the right motivation while reciting mantras (prayers). In contrast, GMP is mainly concerned with cleanliness and hygiene, which translates into the need to create new special factories and to invest in machines for the production and packaging of medicines. This not only alters what are considered quality Tibetan medicines but also increases their price, making them less affordable for rural Tibetans.

In addition, large-scale production of Tibetan medicine requires large amounts of ingredients. Hardly any of these are cultivated or harvested in sustainable ways in Tibet, straining the sensitive environment of the Tibetan plateau and, together with general environmental degradation, endangering the future supply of raw materials.

—Theresia Hofer

In virtually every instance of the introduction of Western scientific medicine into non-Western societies, the process has been contested on some level. Debates have taken place over the nature and cause of disease, appropriate therapies, the legitimacy of native healers, and coercive public health measures. Non-Western societies also have

struggled with implementing scientific medicine's requisite institutional infrastructure and accepting its intellectual presuppositions. Most notably, governments in China and India have continued to defend the indigenous prescientific medical systems of traditional Chinese medicine and Ayurveda. Offering a model response

➤ MEDICAL TOURISTS—NEW MEDICAL INDUSTRIES IN EAST ASIA

Medical tourism, sometimes called medical value travel, represents a growing international trend in health care as well as big business for some countries. Travelers combine elective or nonelective procedures with vacations or simply enjoy high-quality health care at lower prices than in their home countries. As international travel becomes cheaper and easier and as medical standards rise in developing countries as well as in industrialized ones, this new business is thriving and changing the structure of international health care.

Until recently, Singapore, Thailand, India, the Philippines, and Malaysia dominated the Asian medical travel industry. However, medical tourism in East Asia is developing rapidly, with mainland China, Hong Kong, Taiwan, and South Korea growing in popularity for procedures ranging from kidney transplants to face-lifts. In East Asia, well-trained doctors and specialized hospitals at low prices attract overseas patients who are uninsured or underinsured, too impatient or needy to wait for state hospital care, or question the quality of care in their home countries. But here as elsewhere, some hospitals further sweeten the medical tourism experience with luxuries such as private hotel suites, personal nurses, or vacation arrangements.

East Asian hospitals now serve a new market of foreign patients, often themselves from Asian

countries or from the Middle East. In Hong Kong, medical tourism is now estimated at about 6 percent of the private health care market. Clients there include Japanese expatriates and mainland Chinese citizens, especially for childbirth. Taiwan, with its Mandarin fluency, also hopes to attract some of the wealthy mainland Chinese market if cross-strait travel restrictions ease. Other developing East Asian medical tourism industries have been dogged by ethical queries, for instance about organ transplants in China and faked stem cell therapy results in South Korea.

Critics say that provider countries often have inadequate health care for their own citizens and warn of increased risks in traveling overseas for health care, including linguistic and cultural misunderstandings, problems maintaining continuity of care, increased risk of infection, or other problems related to travel after surgery and lack of legal recourse in case of malpractice. Others champion the development of a free market for health care, arguing that it forces hospitals and governments around the world to be more efficient and provide the best care for less money. Already in the United States, some employers and insurers are offering health care outsourcing options for employees.

—Kimberly Dukes

adopted by other countries around the world, China and India have provided legal, financial, and institutional support to preserve traditional medicine while incorporating the unquestionable contributions of medical science.

—Eric W. Boyle

Globalization of Disease

In the era since 1945, with the aid of the World Health Organization and numerous nongovernmental organizations (NGOs), diseases such as

► CENTERS FOR DISEASE CONTROL AND PREVENTION (CDC)

The Centers for Disease Control and Prevention (CDC) is headquartered in Atlanta, Georgia. It is an operating unit of the U.S. Department of Health and Human Services (HHS). The CDC was established in 1946 with a mission of controlling malaria, then a major problem in the southern states. Since that time its mission has expanded to protecting the health and safety of the American people as it seeks to control chronic diseases, injuries, workplace hazards, disabilities, and environmental health threats.

The CDC does extensive research into viruses and other pathogens that threaten both human and animal health. It works with other centers such as the U.S. Army Medical Research & Materiel Command (USAMRMC) at Fort Detrick, Maryland, and the National Institute for Health (NIH), as well as foreign organizations such as the Prince Leopold Institute for Tropical Medicine (ITM) in Antwerp, Belgium, the World Health Organization (WHO), and other research centers around the world. The work of the CDC puts it on the forefront of public health work aimed at the prevention or control of infectious diseases. It conducts numerous research projects on well-known diseases as well as on emerging viruses such as the Human Immunodeficiency Virus (HIV/AIDS), Lassa or Ebola fevers, West Nile Virus, and mutating influenza strains.

Part of the work of the CDC is the training of physicians, nurses, and other health care professionals in new or emerging disease threats. Every year a steady stream of physicians or other health care workers receive training in Atlanta or at other facilities in matters related to deadly disease. In addition, the CDC in cooperation with 12 other HHS agencies sends investigators to remote corners of the world in search of sources of threatening diseases. The dangers of Avian Influenza or the mutating strains of a virus that could cause a global pandemic are of especial concern to its research scientists and to policy makers as well as to the public at large.

—Jack Waskey

smallpox have been eradicated through far-reaching vaccination campaigns, while other diseases, such as polio and measles, have been drastically reduced. However, new diseases have emerged from a number of sources to plague humans, animals, and plants, with globalization a major cause of their spread.

Globalization has permitted people, goods, animals, plants, capital, and diseases to move across political and geographic boundaries. Increased trade in economic goods has been accompanied by increased trade in pathogens. Also, low-cost travel in the modern era has allowed infectious diseases caused by viruses, bacteria, molds, fungi, or other pathogens to spread. They are usually spread by one of five vectors: by contact with pathogens that are airborne, waterborne, or bloodborne; direct contact with a sick individual; or contact with infectious agents such as insects or sick animals. As humans travel to and commercially develop remote areas, chances increase that previously unknown pathogens will be encountered. Some airborne diseases such as Ebola or the other hemorrhagic viruses are very deadly. However, quarantining infected patients allows the disease to exhaust the supply of potential victims.

Some diseases (as well as environmental woes) have been spread via the planned or unplanned importation of insects, animals, or diseased plants into a new country or continent. West Nile Virus was unknown in the Western Hemisphere until it was brought to the United States by some as yet unidentified source. Some diseases jump species to become infectious to new groups and, again, spread more easily as a result of global trade. Migratory birds can carry influenza strains that affect only birds on their migrations. However, the influenza strains could destroy domestic flocks of birds such as chickens, turkeys, or other birds. In addition, in areas such as South Asia great flocks of ducks can be infected and transmit or receive virus strains from pigs that can then be transmitted to humans in tainted food supplies that circulate along global networks. Many of the diseases of the digestive system are spread by infected food or water supplies.

The deadly HIV/AIDS epidemic offers a casebook account of the connection between glo-

Veterinarians wearing protective clothing walk past a barrier with a warning sign that reads "area infected by bird flu" in a northern province of Vietnam on November 5, 2005. (Hoang Dinh Nam/AFP/Getty Images)

balization and disease. The sexually transmitted HIV/AIDS virus takes years to develop, particularly when treated with expensive drugs, but will continue to be deadly to millions globally until vaccines and cures can be developed. Other sexually transmitted diseases have reemerged because of the development of resistance to the drugs used to treat them and because of ease of travel to areas where trafficking in prostitution is common or where sex tourism may be a well-developed industry.

Some diseases also have developed because of the adoption globally of popular but less healthy lifestyles. For example, heart disease is now a global disease that is due to sedentary urbanized lifestyles. The pharmaceutical industry, ironically, despite its successes, has also helped foster more powerful drug-resistant disease strains. Of great concern to health officials, for example, is influenza. The problem with influenza is that vaccines have to be annually tailored to the mutations in the virus strains.

Of great concern to health officials globally is the enormous population growth in the world that has led to huge slums in megacities. These areas are likely places for diseases to mutate and to become the source of deadly global pandemics.

The World Health Organization and Epidemics

Founded in April 1948, the World Health Organization (WHO), part of the United Nations (UN) system, is charged with monitoring and improving public health around the globe. WHO produces health guidelines and standards to help countries address public health concerns. Initially, WHO focused on malaria, tuberculosis, venereal disease, nutrition, and environmental sanitation as well as women's and children's health care.

In the decades since its establishment, the organization has taken numerous steps to respond to the threat posed by epidemic diseases. WHO, for example, took over responsibility from the defunct League of Nations for the preparation and publication of the *International Classification of Disease* in 1948, helping to standardize disease detection and quickly identify health concerns. WHO created a global control program in 1952 for the disease yaws. The disease, which crippled and disfigured about 50 million people in 1950, can be treated with penicillin. By 1965 the incidence of yaws had dropped by more than 95 percent overall in 46 countries. WHO had similar success with its onchocerciasis (river blindness) eradication program in West Africa. The program, begun in 1974, is estimated to have protected 18 million children from the disease over 30 years. WHO

SEVERE ACUTE RESPIRATORY SYNDROME

On November 22, 2002, Chinese physicians diagnosed the first case of an atypical pneumonia later labeled Severe Acute Respiratory Syndrome (SARS). SARS cases continued to multiply until Chinese health officials proclaimed a public health emergency in January 2003. By March, the disease had spread through much of China, Singapore, Taiwan, and Vietnam. The first case outside of Asia was an elderly woman who returned home to Toronto in late February from a trip to Hong Kong, dying two weeks after her return.

As a previously unknown virus, SARS required extensive information sharing and debate among health care workers. The resulting face-to-face meetings and close working conditions among health care workers facilitated the spread of the disease. Medical professionals eventually comprised nearly half of the SARS patients in both Canada and China.

The Canadian outbreak demonstrated the difficulties involved in facilitating quarantine compliance. During the epidemic, more than 30,000 people in the greater Toronto area were placed under quarantine restrictions. After the restrictions were lifted, city officials concluded that a significant number of people had violated the orders, mainly in order to obtain basic supplies (such as groceries) or to avoid losing income. Provincial and local officials determined that improving compensation for quarantined individuals might improve compliance.

The dissemination of the disease's Asian origins provoked a widespread fear of interaction with Asians, resulting in boycotts of Asian restaurants and businesses. Several Asian community leaders in Toronto accused the Canadian government of failing to combat rumors that Asian Canadians were the source of the outbreak, which fueled widespread anti-Asian discrimination and xenophobia throughout Canada.

—Katherine J. Worboys

coordinated the fight against smallpox between 1967 and 1979. The eradication of the age-old menace is the first instance of the worldwide elimination of a major infectious disease. The Global Polio Eradication Initiative, established in 1988, has dramatically reduced the number of cases of poliomyelitis through immunizations.

The rise of globalization has contributed mightily to the spread of infectious disease and complicated WHO's efforts. As the spread of HIV, first identified in 1983, has illustrated, a disease can now move rapidly around the world, emerging or reemerging anywhere. With the increased ease of air travel and the growth of international trade, infectious diseases, such as pandemic influenza, have more opportunities to spread than in previous eras. It is more effective to help other countries control or prevent dangerous diseases than to try to prevent their importation. The WHO approach to HIV/AIDS is typical of its attack on epidemic disease. It stresses prevention, rapid treatment, a special effort to protect women and children, and preempting epidemics by detecting them and acting swiftly to stop them. WHO has established HIV/AIDS teams in 85 countries to advise governments on prevention, treatment, and care. Country offices that need additional technical or financial help turn to regional HIV/AIDS teams in each of WHO's six regional offices. The HIV team at WHO headquarters in Geneva sets global policies and standards, helps mobilize technical support, monitors progress, and obtains political support.

The major epidemic threats at the start of the twenty-first century were pandemic influenza, Rift Valley Fever, Ebola hemorrhagic fever, Marburg fever, malaria, poliomyelitis, and the possibility of intentional releases of biological agents. WHO set a target date of 2015 to stop the spread of malaria and other major diseases. The SARS (Severe Acute Respiratory Syndrome) coronavirus, a killer epidemic that caused considerable global fear in 2003, ceased to be a severe threat because of WHO eradication efforts. WHO's Epidemic and Pandemic Alert and Response (EPR) helps countries prepare for epidemics and develop response plans. The EPR supports epidemic training programs, coordinates international responses, and develops standardized readiness approaches to major epidemic-prone diseases such as meningitis and yellow fever. In addition, the EPR strengthens biosafety, biosecurity, and readiness for outbreaks of emerging epidemics of such viral hemorrhagic fevers as Marburg and Ebola.

Much of WHO's attention in the early twenty-first century was devoted to avian influenza. Pan-

demic influenza has historically been a major killer, one that strikes down otherwise healthy adults in a matter of days. There is little doubt in the medical community that a pandemic influenza will strike again; only its timing, severity, and exact strain remain unknown. If a pandemic is severe, the effects of it will be far-ranging. Accordingly, WHO developed a pandemic influenza program that conducts influenza surveillance around the world, attempts to make genetic matches of influenza vaccine and current influenza viruses, and helps nations develop influenza control strategies and plans. WHO experts anticipate a gap between the supply of vaccine and the demand for vaccine. To reduce the impact of an influenza pandemic, WHO recommends a nonpharmaceutical approach such as infection control as well as a pharmaceutical approach such as the use of vaccines and antivirals for treatment and prophylaxis. The widespread nature of a pandemic means that there will be insufficient production capacity to supply everyone seeking vaccine with medication, at least in the initial months of an outbreak. WHO has developed a Global Vaccine Action Plan to increase the supply of a pandemic vaccine and thereby reduce the expected gap between supply and demand.

Vaccines offer the best means of stopping infectious disease. Under the WHO system, countries send influenza specimens to the agency, which then makes these samples available to the global community for public health purposes, including vaccine development. However, some developing countries have been reluctant to share viral samples for vaccine research because they want to ensure that their citizens have access to vaccines at affordable prices. Indonesia, the nation struck hardest by H5N1, or avian influenza, announced in 2007 that it would not send human bird flu virus samples to WHO unless the agency could guarantee that the specimens would not be used commercially. Indonesia and WHO subsequently came to an agreement that Indonesia would continue to send samples, while WHO would stockpile vaccines in the event of an epidemic. A long-term WHO goal is that developing countries obtain enough technology and scientific training to produce vaccines.

As the situation with Indonesia highlights, developing nations are increasingly uncomfortable

A World Health Organization doctor administers the smallpox vaccination in the Congo in January 1962. (Corel)

with institutions that were designed after World War II for a world dominated by the United States and Europe. Asian, African, and Latin American nations are resisting governing agreements made without their cooperation. It is possible that new public health alliances will be developed in the twenty-first century to give greater power to emerging nations.

Pharmaceutical Advances since 1945

During the second half of the twentieth century, pharmaceutical advances fundamentally reshaped approaches to treating diseases. Drug development during World War II ushered in a

► THE GLOBAL ERADICATION OF SMALLPOX

Smallpox was a deadly disease that was completely eradicated (except for a few laboratory samples) by the World Health Organization (WHO) in 1979. The disease was originally common in Europe, Africa, and Asia and contributed in large part to the devastation of indigenous American populations in the fifteenth and sixteenth centuries. The practice of vaccination for smallpox was created in 1796 by Edward Jenner, who used less-virulent strains of cowpox to inoculate people. In 1958, the Soviet Union proposed to the WHO that smallpox could be eradicated by a mass program of vaccinations in affected countries in the developing world. In 1967, under physician Donald A. Henderson, the program was initiated in earnest. Treatments revolved around vaccinating people recently exposed to the virus rather than inoculating everyone. The smallpox virus was ideal for containment because vaccination gave immunity to all forms of the virus and because it only affected humans. In 1979 the WHO officially declared smallpox eradicated.

revolution in medical therapies and encouraged close associations among academic institutions, governments, and pharmaceutical companies. In a shift from earlier business strategies, pharmaceutical companies began devoting substantial funds to research and development and the discovery of new drugs while employing sophisticated business techniques to market new products to doctors and patients. Major advances in computer technology facilitated laboratory and production automation, revolutionizing the speed at which new drugs could be synthesized and tested.

Beginning in the 1940s, antibiotics revolutionized approaches to medical therapy and inaugurated the first major wave of drug development following World War II. Building on the early success of sulfonamides and penicillin development during World War II, in the 1950s various broad-spectrum antibiotics including tetracyclines and chloramphenicol were introduced in the United States, Europe, and Japan. Tuberculosis, typhus, diphtheria, and other devastating infectious diseases were subsequently largely controlled in

industrialized countries as increased knowledge about human biology and chemistry combined with new technology and instrumentation to make drug discovery more directly focused on targeting specific diseases. Once a researcher identified a new chemical class that was effective against a particular disease state, new prescriptions for ulcers, cancers, diabetes, pain control, and other illnesses followed, as did new vaccines and vitamins.

In the decades immediately following World War II, many pharmaceutical advances stemmed from three primary research and development areas: steroids, psychoactive preparations, and cardiovascular medications. In the 1940s and 1950s, substantial research on steroids and their chemistry produced the anti-inflammatory cortisone as an effective treatment for rheumatoid arthritis. Perhaps the most revolutionary class of steroidal drugs was marketed in the form of the contraceptive pill.

Dramatic advances also came in the area of treating mental disorders. Following the early success of chlorpromazine with psychotic patients, benzodiazepines including librium and valium dominated the pharmaceutical market in the late 1950s and 1960s. By the early 1960s, antibiotics and central nervous system therapies accounted for 44 percent of world drug sales. Meanwhile, as cardiovascular diseases replaced infectious diseases as the greatest killers in Western industrialized countries, pharmaceutical manufacturers developed a new class of drugs in the 1960s, the beta blockers, a major breakthrough in the treatment of high blood pressure and heart disease. In subsequent decades, cardiovascular drugs became the most important source of revenue for pharmaceutical companies globally, accounting for about 22 percent of total sales by the early 1990s.

Additional pharmaceutical advances in the second half of the twentieth century came from a greater understanding of both natural botanical substances and biochemistry. After virtually abandoning natural products in the 1950s and 1960s, success stories with botanical derivatives led many pharmaceutical companies back to this area of research. Taxol, for example, a cancer treatment developed from the bark of yew trees in the 1960s, later became the best-selling cancer

drug in history during the 1990s. In the late 1970s and 1980s new pharmaceutical technologies based on biochemistry, microbiology, and the science of molecular genetics also opened up new avenues in drug innovation. The first major pharmaceutical advance from genetic engineering and recombinant DNA techniques came with a biosynthetic replica of human insulin used in treating diabetes that was marketed in the early 1980s. Additional pharmaceutical advances from this area of molecular research and computer-based discovery in the 1980s and 1990s included a recombinant vaccine for treating hepatitis B, interferon for treating cancer, antidepressants and other serotonin drugs, antiviral drugs for treating HIV/AIDS, and a variety of treatments for high blood pressure, high cholesterol, ulcers, and glaucoma. Advances in molecular science also led to the creation and marketing of many congeners, or me-too drugs, that were molecularly distinct but had identical therapeutic indications.

Pharmaceutical advances have also been accompanied by a series of challenges and critiques. The development of some new drugs, such as thalidomide, have resulted in tragedies. In the late 1950s and early 1960s, thalidomide was sold and prescribed to pregnant women to combat morning sickness and help them sleep. From 1956 to 1962, approximately 10,000 children were born with deformities because their mothers had taken thalidomide while pregnant. Following the thalidomide disaster, widespread regulatory reforms were enacted in several countries, but the recent relaxing of some regulatory measures has revived debates over acceptable levels of risk in research and development. Additionally, the rising price of drugs in both developed and developing countries has also inspired widespread criticism. The pharmaceutical industry has blamed high research and development costs for the rising price of drugs, but critics have pointed to the fact that very little money has been invested in discovering new drugs for diseases that continue to plague developing nations. An analysis of drug development outcomes in the last quarter of the twentieth century showed that only 15 new drugs were indicated for tropical diseases and tuberculosis, which disproportionately affect the poor and represent 12 percent of the global disease burden. By contrast, 179 new

drugs were developed for cardiovascular diseases, which were more common in wealthier nations and represent 11 percent of the global disease burden. While charitable organizations have invested millions in research for neglected diseases including malaria, tuberculosis, and sleeping sickness, in 2003 the World Health Organization estimated that more than one-third of the population in developing countries still lacked access to essential medicines, a reminder that the benefits of pharmaceutical advances have not been fully realized on a global scale.

Genetic Engineering and Its Applications, Post-1945

Genetic engineering involves the alteration of genes for purposes that are not usually part of the organism's original biological function. Genes, which are comprised of DNA, are usually "engineered" through a three-step process. First, they are extracted from the organism's cell (isolation). Then they are manipulated through the process of adding or removing DNA using restriction enzymes (which "cut" DNA) and ligases (which "paste" DNA pieces back together again); this is done to change the genes' DNA sequence and modify its protein expression. Finally, they are reinserted or "spliced" into the original cell, or a host cell, to produce new, or "recombinant," DNA. Genetic engineering is intended to change or improve an organism's function. For example, scientists have used genetic engineering to

➤ GENETIC SCREENING

Genetic screening involves testing an individual's genes, chromosomes, and proteins in order to determine the presence of genetic disorders. Such testing can be used to analyze the genetic material of newborns (to detect illnesses such as phenylketonuria and congenital hypothyroidism); children, adolescents, and adults suspected of having genetic disorders or of being carriers; and the prenatal testing of fetuses whose parents have an increased risk of having a child with a genetic disorder, usually due to the advanced age of the parent(s) or because of a family history of genetic disorders. Prenatal testing involves both invasive techniques such as amniocentesis, chorionic villi sampling, and fetoscopy and noninvasive techniques such as ultrasound and serum testing and is used to diagnose disorders such as Down syndrome, spina bifida, and cystic fibrosis.

Testing involves sampling blood or, in the case of prenatal diagnosis, amniotic fluid and then analyzing it for genetic disorders. To do this, the chromosomes are separated and lined up in a process known as karyotyping; genes/proteins then undergo further analysis through more advanced laboratory testing. If a genetic disease is discovered, the parties involved undergo a

Human karyotype (male) (National Human Genome Research Institute)

process known as genetic counseling, which includes interpreting the results of the testing, discussing the outcomes, and establishing a plan to handle the ethical, physical, psychological, and medical ramifications of the situation.

—Tanfer Emin Tunc

program bacteria to produce human insulin; to genetically modify organisms such as mice, fish, and fruit flies; and to produce more robust crops such as tobacco, tomatoes, and corn.

Modern genetic engineering began in the mid-1950s, soon after James Watson and Francis Crick elucidated the double-helix structure of DNA (1953). However, large-scale experimentation did not occur until 1967, when American scientists isolated the first enzymatic DNA ligase. In 1970, Stewart Linn and Werner Arber discovered that a “restriction” enzyme in the bacteria *E. coli* could be used to cut DNA at specific locations. In 1972, Paul Berg used these new technologies to create the first “recombinant” plasmid (a circular bacterial chromosome). The following year, Herbert Boyer and Stanley Cohen inserted a genetically engineered plasmid into a bacterium to create the first successful recombinant DNA organism. By the late 1970s, advances

in genetic engineering began to occur at a rapid pace: in 1977, Walter Gilbert and Frederick Sanger formulated the technique used to determine DNA base sequences (gel electrophoresis), which Sanger used to determine the entire genome—that is, genetic sequence—of a virus.

Prenatal genetic diagnostic procedures such as amniocentesis and chorionic villi sampling became available in the mid-1970s as scientists discovered how to obtain samples safely, usually through ultrasound guidance, and to analyze human chromosomes for genetic diseases. A few years later, scientists started to experiment with splicing genes from different specimens to create chimera or “hybrid animals” such as rat-mice, sheep-goats, and so on. They also began to use transgenic or genetically modified bacteria to produce lifesaving substances such as insulin. Insulin was first produced in 1979, and the U.S. Food and Drug Administration approved Genen-

tech's Humulin in 1982. Research in genetic engineering was dramatically altered in 1983 when biochemist Kary Mullins formulated the polymerase chain reaction, which gave scientists the ability to replicate DNA at astounding rates. They were now able to use this new tool to develop techniques such as genetic fingerprinting (1984), which was eventually applied to forensics, paternity testing, the cloning of genes, and the creation of genetically modified plants and animals such as pigs, bulls, and "oncomice," which were specifically developed for use in cancer research.

In 1990, James Watson initiated the Human Genome Project, a global collaboration of scientists who spent the next 13 years mapping the human genome. Completed in 2003, the results of this revolutionary venture have facilitated breakthroughs in almost all branches of human genetic engineering. The development of gene therapy, which involves the substitution of an "abnormal" disease-causing gene with a healthy gene, usually through carriers known as vectors, has been one of the benefits of mapping the human genome. Now able to locate the position of disease-causing genes, scientists are using gene therapy to treat diseases such as cystic fibrosis, sickle cell anemia, thalassemia, and breast cancer.

Within the past decade, scientists have also used genetic engineering techniques to alter the meaning of reproduction. In 1997, Scottish researchers created "Dolly," the first sheep cloned using the nuclear transfer technique, while "Polly," who was born in December of the same year, became the first transgenic cloned sheep. In 2004, scientists in South Korea reported cloning the first human embryos. Several years earlier, in 2001, the American laboratory Advanced Cell Technologies reported cloning a human embryo using the "Dolly" method, but it only made it to the six-cell stage before dying. "Designer babies," that is, fetuses that have been preselected based on pre-implantation genetic diagnosis and cloning, have become visible examples of new reproductive technologies.

The hype over Dolly, Polly, and genetically modified babies—or fetuses containing the DNA of more than two parents—has reignited the ethical debates over genetic engineering. Human cloning is enraging individuals across the politi-

cal spectrum. Many humanitarians are concerned that cloning violates the sanctity of life. Recent experiences involving the termination of pregnancies because of the fetus's sex, particularly in China and India, raise further concerns. In some quarters, there is also a concern about removing control of reproduction from women in favor of scientists, presumed to be primarily male. Accusing scientists of "playing God," opponents of genetic engineering are not only voicing their opinions through the media but are also persuading governments all around the world to enact legislation regulating or criminalizing genetic research, especially on human cloning. Stem cell research, which involves genetically programming "blank" human embryonic cells with the hope of treating illnesses such as cancer, Parkinson's disease, and spinal cord injuries, has, not surprisingly, met with similar reactions. It is only the latest ethical quandary in what is sure to be many more decades of controversy for this revolutionary branch of science.

Surgical Advances, 1945–Present

By the 1950s because of previous advances in anesthesia and postoperative care, surgery was already a well-established and well-respected discipline. The second half of the twentieth century witnessed further growth of surgery into previously unexplored areas. Technical advances enabled surgeons to operate on organs such as the heart, a feat that had previously been considered to be impossible. After World War II transfusions became safer, and the use of fluid-replacement

► HEART TRANSPLANT PIONEERS

In December 1967 Christiaan Barnard (1922–2001), a South African surgeon working at the Groote Schuur Hospital, performed the first successful heart transplant procedure. Operating on Lewis Washkansky, a 53-year-old male who faced certain death from heart failure, Barnard replaced the failing heart with a healthy heart from a 25-year-old woman who had died after an automobile accident.

Although this first heart transplant patient only lived for 18 days, Barnard achieved instant fame because he had proved that an unthinkable operation was now possible, offering hope for thousands of patients with previously incurable heart disease. Barnard's astonishing achievement was feasible because of two advances: (1) availability of mechanical equipment to substitute for the heart and lungs while replacing the defective heart and (2) immunosuppressive drugs such as cyclosporine, azathioprine, and prednisone to prevent rejection of the foreign organ.

Initially the procedure was rarely used because survival rates were less than 20 percent, with fatalities mainly caused by rejection of the new organ. However, the operation became acceptable after development of newer immunosuppressive drugs that offered much better control of the rejection phenomena. Since Barnard's historic first operation, heart transplantation has become a recognized surgical procedure available for the

Surgeon Christiaan Barnard shows an X-ray image of Louis Washkansky's chest taken during the first heart transplant December 5, 1967. (Bettmann/Corbis)

management of intractable heart failure. At present in the United States, 87 percent of heart transplant patients survive for one year, and more than two-thirds of patients survive for five years. The major limitation now is not related to rejection or technical problems but rather a shortage of suitable donor hearts. In the United States from 1988 to 2004, 36,000 cardiac transplants have been performed. More patients could be treated, but a shortage of suitable donor organs limits the opportunity for cardiac transplantation to about 2,000 patients per year.

—Albert B. Lowenfels

therapy for the management of shock improved the chances of survival for severely injured patients.

The rapid expansion of surgery since the 1950s coincides with advances in seemingly unrelated specialties. The results of all types of surgery improved in the 1950s after the development of antibiotics, which lowered the infection rate after surgery, and the availability of drugs to reduce the formation of potentially fatal blood clots that often develop after an injury or operation. Largely because of the development of immunosuppressive drugs that allowed the body to tolerate foreign tissue without rejection, surgeons could replace a failing organ with a

healthy donor organ. The kidney was the first organ to be successfully transplanted, with the initial patient receiving a healthy organ from his identical twin brother; over time, organs from unrelated donors were successfully transplanted. In 1990, Joseph Murray, because of his pioneering achievements in transplantation, received the Nobel Prize in Medicine. Successful renal transplantation led to replacement of other failing organs such as the liver, intestine, and pancreas. Now even the heart can be transplanted with relative safety. Patient survival after organ replacement has steadily improved over time.

In the second half of the twentieth century surgical diagnosis also became much more accu-

rate. Surgeons and surgical specialists now have greatly enhanced diagnostic tools such as mammography for the early diagnosis of breast cancer and newer types of scans such as computerized tomography (CT) to detect occult lesions hidden deep within the various body cavities. These new modalities greatly improve the surgeon's ability to pinpoint the exact nature and location of the patient's pathology.

Technologic advances have simplified surgery and improved patient recovery. Since the 1950s new tools such as surgical stapling devices to control internal hemorrhage or to reunite parts of the intestinal tract have simplified abdominal surgery. Laser devices are widely used, especially by ophthalmologists. Laparoscopic or minimal-access surgery has dramatically changed the way surgeons perform many of the most common operations. For example, removal of the gallbladder (cholecystectomy) traditionally required a large and painful abdominal incision followed by prolonged hospitalization. Today, most of these operations are carried out through tiny incisions to allow the surgeon to insert a small television camera inside the abdomen to visualize the organs and to allow use of long, narrow specially designed instruments. Patients are more comfortable and recover more rapidly after minimal-access surgery.

Perhaps the most dramatic technological advance has been the development of robotic surgery whereby the surgeon, seated at a computer console, sends instructions to specially designed instruments that perform the operation by following the surgeon's electronically submitted commands. No longer does the surgeon have to be in the same location as the patient. In 2001 a surgeon in the United States relying on robotically controlled instruments removed the gallbladder from a 68-year-old patient hospitalized in France.

In the latter half of the twentieth century surgical specialists developed numerous new operations. Pediatric surgeons can now successfully treat many birth defects, and today it is even feasible to perform fetal surgery. Orthopedic surgeons easily replace painful arthritic joints such as the hip, knee, or shoulder with a new highly functional synthetic joint. Surgeons have devel-

oped new operations to manage the growing number of patients with life-threatening obesity. Ophthalmologic surgeons have transformed cataract surgery into a safe, effective ambulatory procedure. Neurosurgeons have benefited from the development of diagnostic procedures to accurately locate and treat brain lesions.

The development of machines to temporarily substitute for the heart allowed cardiac surgery to develop. During open heart surgery, heart-lung machines shunt blood away from the heart while the surgeon repairs congenital defects or damaged heart valves or replaces occluded coronary blood vessels.

The advances in surgery that have taken place since the 1950s are well illustrated by Albert Einstein's final illness. In 1948 Einstein developed an aneurysm, or dilatation of his abdominal aorta, a disease with the risk of eventual rupture and fatal hemorrhage. At that time no definitive treatment for this life-threatening illness was available, and Einstein died in 1955 when his aorta ruptured. Only a few years after Einstein's death, surgeons developed a procedure to replace the swollen part of the aorta with a cloth graft. Remarkably, in the twenty-first century, a new breakthrough occurred. Rather than the formidable task of replacing the aorta, surgeons obtain excellent results by strengthening the bulging aorta internally with an expandable graft placed inside the damaged blood vessel. This has become a common operation because it can be done with minimal blood loss through small groin incisions, making it ideal for elderly poor-risk patients.

Folk Medicine since 1945

The second half of the twentieth century represented a crossroads for folk medicine. Mass-marketed pharmaceutical drugs and the encroachment of Western scientific medicine threatened the preservation of many traditional or folk systems of medical knowledge. This crisis, however, also stimulated intensive studies of folk medicine by scholars in a variety of academic disciplines in the 1950s and 1960s. Anthropologists, historians, archaeologists, and sociologists responded to the widespread loss of traditional cultural knowledge and practices by gaining a greater understanding of folk medical beliefs and practices in Europe, Asia, Africa, Polynesia, and the Americas. Armed with this knowledge, scientific researchers turned to studying the plant world as a source of new medicines in the 1980s and 1990s. At the end of the twentieth century, scientists demonstrated the effectiveness of hundreds of folk medical treatments used around the world since the beginnings of recorded history.

Ethnobotanists, who study how different cultures' use of plants, were among the scientists who sought to document and preserve indigenous medical practices. Richard Schultes, often called the father of ethnobotany, spent 13 years in South America, from 1941 to 1954, and collected 24,000 plant specimens, including 2,000 used by traditional healers. The collection is still being studied for undiscovered new medicines. In the early 1940s additional pioneering work by ethnobotanist Russell Marker with Mexican yams reminded practitioners of Western scientific medicine that folk medicine still had much to offer. Marker developed a technique for turning the crude active substance in Mexican yams into the steroid progesterone. Shortly thereafter, Syntex, a new company jointly founded by Marker and Mexican scientists, developed a synthetic cortisone and a hormone that inhibited ovulation, making Syntex the world leader in steroid chemistry. By the early 1960s Syntex was supplying the hormones for half the world's market in oral contraceptives. The success of Syntex was not replicated in subsequent decades, and much of Schultes's pioneering work went unrecognized.

Richard Evans Schultes at Yapobodá, in the Northwest Amazon, 1946. Schultes (1915–2001) is widely considered to be the founder of ethnobotany studies. (Smithsonian Institution)

During the 1980s and 1990s a combination of events led to a widespread revival of interest in folk medicines. Alarmed by the rate of rain forest destruction, environmentalists and scientists combined forces. At the same time, pharmaceutical companies began to see the value in returning to the analysis of plant compounds for new drugs. By this time, much progress was made in understanding the mechanisms of diseases such as cancer, heart disease, arthritis, and mental illness. Medical scientists developed a new approach to scan the thousands of compounds found in nature for drugs to target those disease mechanisms, a process called mechanism-based screening.

Inspired by the promise of medicinal botany's past, a new era of medicine hunting led to the phenomenon called biodiversity prospecting. The prospectors included ethnobotanists, biologists, and anthropologists. They mined tropical rain forests and discovered active compounds used to treat dozens of conditions and diseases includ-

ing high cholesterol, respiratory ailments, herpes, and cancer. Biodiversity prospecting has subsequently extended far beyond the rain forests. Scientists built on earlier studies that meticulously documented and demonstrated the efficacy of Amerindian, Asian, African, Indian, and European folk medicines originating in classical antiquity. Using clinical trials and molecular science to isolate and test the active ingredients in plants, they embarked on efforts to adapt these folk remedies for widespread use. Their work continued in the early twenty-first century.

The widespread revival of interest in folk medicine inspired by researchers was accompanied by international debates over the value of folk medicine and the control of indigenous knowledge in the last quarter of the twentieth century. In 1977 the World Health Organization (WHO) signaled a major shift in popular perceptions by officially endorsing the principle that many folk medicines could be used as safe and inexpensive alternatives to Western scientific medicine. In 2002 WHO launched its first comprehensive strategy to help countries preserve folk medicines, with additional goals to ensure availability and affordability while developing national policies on the evaluation and regulation of traditional medicine.

Meanwhile, disputes have continued over intellectual property rights and the control of indigenous folk medical knowledge. In 1981 the Model Law for the Protection of Expressions of Folklore against Illicit Exploitation and other Prejudicial Actions was jointly adopted by the World Intellectual Property Organization and the United Nations Educational, Scientific and Cultural Organization. In 1992 the Convention on Biological Diversity also specifically addressed the problem of unauthorized appropriation of traditional knowledge in order to ensure that indigenous populations would share in the benefits through a system of equitable distribution. In order to foster a dialogue about equity between developed and developing nations, the Intergovernmental Committee on Intellectual Property and Genetic Resources, Traditional Knowledge and Folklore was also established by the World Intellectual Property Organization in 2000. At its first meeting in 2001, debates over how to create international standards for the legal protection

➤ COCA LEAF AND INDIGENOUS MEDICINAL PRACTICES IN THE ANDES

Coca leaf, one of the world's first domesticated plants in the Americas, has been cultivated, traded, and used in medicines and ceremonies by Andean peoples for more than 4,000 years. Unfortunately, the Western world associates the plant primarily with its notorious derivative, cocaine. The leaf's tiny concentration of the cocaine alkaloid plays a role in its pharmacological properties, as when the leaves are used as a poultice for minor wounds or as a topical anesthetic. The drug cocaine, however, was a Western laboratory invention—extracted in 1860 by a German chemist—and has no corollary in Andean traditions.

Coca leaves are most commonly used as an herbal tea to ameliorate the effects of high altitude or indigestion and as a mild stimulant—with an effect similar to caffeine—when chewed during work in the fields, mines, and markets. The coca leaf is not addictive, as are both caffeine and pure cocaine. Traditionally, coca was also chewed after meals, which in the Andes consisted primarily of potatoes, and coca has been found to help regulate the blood sugar produced by potato starch. Because coca leaf has so many quotidian uses, it holds a central place in Andean spirituality and is considered the sacred leaf. Myths explain that coca was a gift to humankind from Pachamama (Mother Earth), so indigenous people continue to give offerings of coca leaf to Her during celebrations.

The legends that express reverence to coca represent deep cultural knowledge, for the leaf has been found to contain many essential vitamins and minerals that indigenous people could not access in the rest of their diet in ancient times and often cannot afford to access now. For example, coca is high in calcium, and milk products did not exist before the Spanish conquered the Andes in the sixteenth century; milk is also too expensive now for many to consume regularly. A major Harvard study showed that compared to 50 other native plants consumed in the Andes, coca leaf has higher concentrations of proteins, carbohydrates, fiber, calcium, iron, and vitamins A, B-12, and E. Coca's superior nutritional value thus complements its excellent medicinal qualities, making it seem like the sacred leaf indeed.

—Caroline S. Conzelman

of folk medicine as intellectual property continued. Early twenty-first-century estimates suggest that more than half of the world population relies on traditional healers and folk medicine for a wide variety of illnesses. While the future of folk medicine remains uncertain, these forms of medicine and therapeutic regimens have sparked widespread interest in the West. From traditional Chinese herbs and acupuncture to indigenous practices and Western folk cures, they represent alternatives to conventional scientific medicine with growing popularity in developed nations.

AIDS and Poverty

As of 2006, 40 million people around the world were living with the human immunodeficiency virus (HIV), with the burden of the disease falling most heavily on developing countries. The pandemic is particularly devastating in sub-

Saharan Africa, where the HIV adult prevalence rate approaches 6 percent, far higher than on any other continent. When the virus progresses to the stage of acquired immunodeficiency syndrome (AIDS) and goes untreated, it causes death within a year on average. In 2006 there were 2.9 million AIDS deaths around the world, and almost three-quarters of them were in sub-Saharan Africa.

Experts have not been able to pinpoint the exact origins of the HIV virus but suspect that a trans-species jump from chimpanzees to humans occurred in West-Central Africa sometime during the twentieth century. Subsequent worldwide transmission of the virus has been the result of unprotected sexual activity; intravenous drug use involving nonsterile needles; mother-to-infant infection during pregnancy, childbirth, or breastfeeding; and contaminated blood transfusions (now rare). The virus cannot be spread through casual contact, such as handshakes or coughs. Another common misconception is to view AIDS as a homosexual disease. Globally, the virus is transmitted heterosexually in the majority of cases. In sub-Saharan Africa, women living with HIV now outnumber men in a ratio of six to four.

It is estimated that since the initial scientific recognition of the disease in the early 1980s, AIDS has claimed 25 million lives, making it one of history's most lethal epidemics. The toll has been severe, individually and at national and regional levels. Because of the specific ways that it spreads, HIV tends to impact young adults disproportionately, compounding the economic, social, and demographic costs of the disease. In countries with high infection rates, the illness is ravaging household incomes. Without strong systems of state-funded education, many families must withdraw their children from school. When one or both parents are incapacitated by AIDS, children are deprived of material and emotional support. Africa now has millions of AIDS orphans. Another demographic effect of AIDS is seen in reduced life expectancies. In several nations in Southern Africa, AIDS has been a major factor in the lowering of life expectancies to below 40 years of age, the lowest levels in the world and a stunning reversal of the modern trend toward longer lives.

➤ TIMELINE OF AIDS EPIDEMIC

- 1959—A blood sample is taken, which in 1986 tests positive for Human Immunodeficiency Virus (HIV).
- 1984—First AIDS conference held in Atlanta, Georgia.
- 1986—The clinical trial for the first antiretroviral drug, zidovudine (AZT), is complete.
- 1989—According to World Health Organization estimates, worldwide 480,000 people live with HIV and AIDS.
- 1991—Worldwide, 2.9 million people living with HIV and AIDS.
- 1994—AZT is shown to reduce mother-child transmission of HIV by 67.5 percent. Eleven million people with HIV and AIDS, 65 percent of the global total, live in sub-Saharan Africa.
- 1996—Brazil launches nationwide antiretroviral drug distribution and AIDS care and awareness program.
- 1999—In Russia, 12,000 new cases in 10 months are blamed mostly on drug injections within the military.
- 2000—“Debate on Impact of AIDS on Peace and Security in Africa” marks the first time in 50 years that the United Nations Security Council meets to discuss a public health issue.
- 2001—Bristol-Myers Squibb, a pharmaceutical company, offers to reduce stavudine and

didanosine therapy costs in Africa to \$1 per day per patient. Abbott Laboratories offers its antiretroviral drugs at no profit in African countries.

—AIDS is declared the main cause of death in Thailand.

—An estimated 40 million adults and children worldwide have HIV and AIDS.

2003—The U.S. Senate approves a \$15 billion emergency plan for AIDS relief, to be spent over 5 years. Of this, \$3 billion is to be distributed each year to the African and Caribbean countries worst hit by the HIV and AIDS epidemic.

2006—Estimates of the number of people living with HIV and AIDS range from 34.1 million to 47.1 million (www.unaids.org).

Bibliography

“Global Summary of the AIDS Epidemic, December 2006.” data.unaids.org/pub/EpiReport/2006/02-Global_Summary_2006_EpiUpdate_eng.pdf.

Marlink, Richard G., and Alice G. Kotin. “Global and Regional Responses to HIV and AIDS.” *Global AIDS Crisis: A Reference Handbook*. Santa Barbara, CA: ABC-CLIO, 2004.

The economic damage from HIV/AIDS varies from country to country. Where prevalence rates are highest, the damage is greatest. The disease cuts into the labor force in unpredictable ways, deprives employers of experienced workers, and drives up recruitment and training costs. Workers are lost not only to the disease but to caretaking duties for family members. As incomes fall, so does spending. Economic growth rates are being reduced in places where living standards are already among the lowest in the world. Governments are having to divert much-needed funds from physical and social investments to AIDS prevention, relief, and care.

The picture is not entirely grim. Although the disease is at present incurable, it is treatable and preventable. Antiretroviral drug treatments, which have been greatly improved and

A banner to help combat the spread of AIDS is displayed on the border of the Naledi township in Gaborone. More than one in four adults in Botswana is infected with the HIV/AIDS virus, according to official statistics, making it one of the world's worst-affected countries. (AFP/Getty Images)

simplified, can slow the onset of AIDS symptoms in those who are HIV-positive. Such drugs are extending many lives. Their cost remains a problem in poor nations, but low-cost generic substitutes are becoming more available. Ultimately, the hope is for an effective AIDS vaccine. Experts caution that there are major technical hurdles to be overcome, yet several vaccine trials are now under way. The other way to achieve prevention is through education efforts aimed at changing behavior to reduce the risks of HIV transmission. Needle exchange programs can lower that risk; so can the consistent use of condoms, faithfulness to one's sexual partner, and male circumcision. The establishment of the Global Fund to Fight AIDS, Tuberculosis and Malaria in 2002 signaled a new international commitment to mobilize financial resources for the prevention and treatment of these diseases. Major funding for the Global Fund has come from the governments of the United States, Japan, and several European nations as well as the Gates Foundation.

HIV/AIDS now ranks as one of history's most devastating pandemics. Its capacity to elude a cure, decade after decade, sets it apart from most other communicable diseases that have afflicted humanity. Its disproportionate impact on Africa, the world's poorest continent, will be noted in every history of our time.

National Health Care Systems since 1945

With the emergence of the welfare state in Western Europe (e.g., Britain, France, and Germany) and the United States (under the New Deal) in the late nineteenth century to the first half of

the twentieth century (mostly in the form of unemployment insurance and old age pensions), the basic requirements for medical care continued to be covered at cost by patients, with some level of coverage through private insurance or their own savings. The ability to pay dictated the level of care that was available to the patient-consumer. Much of the colonized world lacked basic medical facilities to meet the demands of illnesses and injury, which put people at peril, much more so when they lacked the ability to pay. With the end of World War II, national health care systems were created throughout much of the developed world, albeit at differing levels of state agency and private initiative, in order to meet the medical, dental, and mental health issues of their respective populations.

Socialized health care systems were established in postwar Europe as part of the development of the welfare state. In 1946, Britain established the publically funded National Health Service (NHS), which offered comprehensive medical, dental, mental health care, and prescriptions, nominally free of charge to all British citizens, through the passage of the National Health Service Act. British prime minister Clement Attlee's Labour government created the NHS as part of the cradle-to-grave welfare state envisioned in the wartime Beveridge Report. The NHS established state-run hospitals, medical facilities, and teaching hospitals and made agreements with physicians, dentists, and other medical practitioners, essentially making them public servants. Private general practitioners (GPs) were allowed to continue their service albeit under government regulation and with their services paid by the state. Moreover, private insurance continued to function, albeit as an adjunct to NHS benefits. France, West Germany, Japan, Sweden, Australia, and other developed states established comparable health care systems by instituting social insurance legislation under the direct authority of their national governments. Marxist-Leninist East European states and the Soviet Union, while also establishing and expanding their health care systems for their respective populations, placed economic development as a higher priority of the state and thereby reduced the amount of service available to the people.

Single-payer health care systems were developed in North America and Oceania that offered publically funded health care without making medical facilities de facto government agencies, as in socialized health care systems in Europe. In North America, both the United States and Canada established health care systems with differing levels of government involvement. The United States instituted Medicare as part of the Social Security Act of 1965 under the auspices of Lyndon B. Johnson's progressive social policies known collectively as the Great Society. Medicare was established as a single-payer national health insurance plan (meaning that the government would pay for services in the private sector) for people ages 65 or older who met certain criteria for eligibility. Medicaid, which was also established that year, served to provide low-income families with health care through federal funds managed by individual states, which typically matched federal funds, under federal supervision. Nonetheless, these programs were geared toward certain sectors of the population, meaning that the majority were left to purchase their own health insurance. Those who were not able to afford such a luxury were left to their resources in a medical emergency. In contrast, in 1966, Canada instituted a single-payer universal health care system, similar to U.S. Medicare, but extended to the entire population in providing medical, dental, and mental health care.

Health care systems in the developing world are either absent or severely underfunded. Although Latin American states, such as Mexico, Brazil, and Argentina have extensive government-subsidized health care systems, they are often underfunded. Certain services are entirely absent from public facilities and must be obtained through private at-cost institutions. Thriving Asian states have developed privatized and semipublic health care systems, which often suffer from a

surfeit of funds or services. Some African states only have international nongovernmental organizations, such as the International Red Cross and Doctors without Borders, to provide medical care, particularly in war-torn states such as Congo and Sudan. Moreover, terrorist organizations, such as Hizbullah, offer health care to certain constituencies in Lebanon as a means to ensure support for their cause. India and China have developed public health care systems to meet the needs of their expanding populations, but these are often lacking suitable services and funding.

Public debates over national health care programs have recently become polemic throughout much of the West in light of rapidly expanding aging populations and the waning of public expenditures to meet their health care needs. Britain, France, Germany, and Japan, with large portions of their respective populations graying, will potentially incur huge health care costs to the state and thereby increased taxes. Moreover, as of 2009 in the United States under the administration of President Barack Obama, health care reform planning has led to protests against the perceived socialization of medicine, with the lead protest target a single-payer universal health care system administered by the federal government.

Regardless of public debate over health care systems and the level of state intervention in much of the developed and developing world, after 1945 most governments around the world have assumed the responsibility of instituting state-administered or at the very least privately held state-regulated health care systems.

■ Introduction: Technology, Post-1945

Wartime investments in science and technology led to numerous developments that saved the lives of combatants and noncombatants alike. Everything from penicillin to DDT and from elementary computers to new explosives were applied to civilian life after the end of the war. The Cold War military buildup and ideological struggle continued high levels of postwar funding for science and technology research.

Advances in basic science were applied to many areas of industry or life. The new postwar computers were huge machines such as the Electronic Numerical Integrator and Calculator (ENIAC) at the University of Pennsylvania, begun at the end of World War II as a U.S. Army tool for calculating missile trajectories. It weighed 50 tons and covered 1,800 square feet. Computers were first powered by vacuum tubes, which processed data recorded on punch cards. The development of computers postwar was aided by a number of advances in other sciences. These included at first transistors and then integrated circuit boards. Innovations included the development of silicon chips that contained metal wiring that was printed into the chip.

In the chemical industry, numerous materials were developed, including new plastic resins that were strong, light, and capable of being molded into a virtually limitless number of products. These resins include low-density polyethylene (1942) used in plastic squeeze bottles, polypropylene (1957) used in safety helmets, and liquid crystal polymers (1985) used in electronic parts. Resins such as rayon (1910) and nylon (1939) have been spun into fabrics. While nylon created so-called nylon wars following wartime shortages of silk stockings, spandex (1959) when spun into tight clothing created another fashion stir during the disco era. Other resins have been combined with fabric or fibers to manufacture a wide range of strong, light composite materials such as carbon fibers ideal for use in automotive or aviation production. Other new chemical materials range from Teflon (a solid fluorocarbon) to the engineered spherical carbon molecules known as Bucky Balls or Fullerenes, named after

the somewhat visionary U.S. inventor Buckminster Fuller who developed similar structures on the macroscale for his domes.

Miniaturization has allowed computers to become increasingly small and powerful. With the advance of miniaturization, the cutting edge by the 1990s was found in the new nanoscale science and technology. The full development of nanoscience is still in the future. However, it is the object of great concern for both the profits and the problems it may generate. Nanotechnology involves the manipulation of the materials at the atomic or molecular level. To give one example, it may be possible to develop nanopharma that will specifically target and destroy pathogens or a cancerous tumor. This nanopharma would be specific, unlike the chemotherapies or radiation treatments that have been used to kill cancers while also almost killing the patient with chemical or radiation poisoning.

The expected benefits from nanoscale science such as that of stem cell research are still hopes that will be realized in the future. However, the use of computers in developing new medicines is now standard through a high throughput process that uses the computer to test large numbers of chemicals and their biological responses.

There are hopes that new technologies will aid efforts to create sustainable homes, workplaces, and cities. To give one example, nanotechnology might create so-called smart compounds that could transform the paint of the house or roof into a electrical power plant.

—*Jack Waskey*

Integrated Circuits

Besides creating an enormous consumer electronics industry, integrated circuits had become pervasive in all areas of scientific endeavor by the late 1970s. Integrated circuits are made of wafers of silicon with electronic components, such as transistors, diodes, capacitors, and resistors, etched into the silicon by chemicals or light. The semiconducting nature of silicon is used to direct the flow of electrons through the electronic

components, using binary values and the rules of Boolean algebra, a mathematical curiosity created a century earlier by the self-taught British mathematician George Boole (1815–1864).

The earlier innovation necessary to create integrated circuits was the invention of the transistor in 1947 at Bell Telephone Laboratories in Murray Hill, New Jersey, by William Shockley (1910–1989), Walter H. Brattain (1902–1987), and John Bardeen (1908–1991), for which the three men shared the 1956 Nobel Prize in Physics. Integrated circuits were independently invented by Jack S. Kilby (1923–2005) of Texas Instruments and Robert Noyce (1927–1990) at Fairchild Semiconductor in 1958 and 1959. Kilby obtained the first patent, and Noyce developed the planar process to place metal connections on the semiconductor wafer; royalties were paid to both men for their inventions. Kilby received half of the 2000 Nobel Prize in Physics after Noyce had been dead for ten years.

Fairchild Semiconductor brought the first integrated circuit to market in 1961. The Apollo project became the first big customer for integrated circuits and proved a key driver to accelerate the growth of the semiconductor industry. Quite quickly, integrated circuits became the main technology of the computer industry, and integrated circuits made possible later space exploration. The integrated circuit led to the invention of the microprocessor in the early 1970s at Intel Corporation. A microprocessor combines all the central logic necessary for a computer onto a single chip.

In 1964, Gordon E. Moore (1929–) noticed that the density of transistors and other components on integrated chips doubled every year. He charted this trend and predicted that it would continue until about 1980, when the density of integrated circuits would decline to doubling every two years. Variations of this idea became known as Moore's Law. Since the early 1970s, chip density on integrated circuits, both microprocessors and memory chips, has doubled about every 18 months. About 50 electronic components per chip was the density in 1965, 5 million electronic components were placed on an individual chip in 2000, and in 2008 the number of components had reached 810 million. An individual transistor on a chip is now about 32 nano-

meters in size. At times, different commentators have predicted that this trend would hit an obstacle that engineers could not overcome and slow down, but that has not yet happened. The electronic components on integrated circuits are being packed so close that by the second decade of the twenty-first century it is believed that quantum effects will begin to make it impossible to maintain the rate of increasing density predicted by Moore's Law.

In the late 1990s, the technology used to manufacture integrated circuits was adapted by replacing transistors on the silicon with deposits of DNA. These DNA microarrays, or DNA chips, are used to quickly and simultaneously test a biological substance against thousands of pieces of different DNA, leading to a thousandfold increase in productivity by experimental biologists.

Computers

During World War II, various defense projects in America and Britain developed high-speed electronic calculators, among which were the first digital computers. Earlier computers were either mechanical or analog-based. Digital computers represent data as discrete pieces of information, or bits. These new computers were based on vacuum-tube technologies and experienced frequent failures. Engineers extending the frontiers of their craft, rather than scientists, built these computers.

The first truly digital computer that was more than a prototype was the Colossus, built by the British during World War II to help decrypt

German radio traffic. The British government kept its success a secret for more than two decades, so the first acknowledged digital computer was an American invention. Completed in 1945, the ENIAC (Electronic Numerical Integrator and Computer) was a high-speed electronic calculator designed to create artillery ballistic tables and built by J. Presper Eckert (1919–1995) and John Mauchly (1907–1980) for the U.S. Army at the University of Pennsylvania Moore School of Electrical Engineering. While building ENIAC, Eckert and Mauchly developed for their next computer the concept of a stored program, where data and program code resided together in memory. This concept allowed computers to be programmed dynamically so that the actual electronics did not have to change with every program.

The noted mathematician John von Neumann (1903–1957) expanded on the concept of stored programs and laid the theoretical foundations of all modern computers in a 1945 report and later work. His ideas came to be known as the von Neumann Architecture. The center of the architecture is the repeating fetch-decode-execute cycle: instructions are fetched from memory and then decoded and executed in a processor. The execution of the instruction changes data that are also in memory. Eckert and Mauchly deserve equal credit with von Neumann for their innovations, though von Neumann's elaboration of their initial ideas and his considerable prestige lent credibility to the budding movement to build digital computers. Eckert and Mauchly went on to build the first commercial computer, the UNIVAC (Universal Automatic Computer), in 1951.

The Soviet Union built its first computer in 1950 at the Kiev Institute of Electric Engineering under the direction of S. A. Lebedev; it ran 50 instructions a second and used a memory of 31 16-bit words. After moving to Moscow, Lebedev proceeded to supervise the development of the BESM (the acronym for the Russian-language term for "large electronic computer") series of computers, which used magnetic drums and magnetic tapes for storage.

The transistor was invented in 1947 at the Bell Telephone Laboratories in Murray Hill, New Jersey, by John Bardeen (1908–1991), William

Shockley (1910–1989), and Walter H. Brattain (1902–1987). By the late 1950s, the transistor became a useful commercial product, creating the second generation of computer hardware; it rapidly replaced vacuum tubes in computers and other electronic devices because transistors were much smaller, generated less heat, and were more reliable. Defense-related projects and space-related projects undertaken in the United States as part of the Cold War became a major driver for computer-related innovation in both hardware and software.

The development of integrated circuits in the mid-1960s concentrated transistors on silicon wafers, inaugurating a third generation of computer hardware. In the 1970s, engineers packed enough logic gates onto an integrated circuit to create a microprocessor, or a computer on a chip. Microprocessors led to personal computers and cheap handheld calculators, banishing slide rules to museums. The current fourth generation of hardware is based on microprocessors and ever more sophisticated integrated circuit chips.

The 1950s brought the first higher-level programming languages. FORTRAN (FORMula TRANslator) was invented in 1957 as an easy way to write mathematically oriented scientific programs. The 1960s brought time-sharing systems and the development of operating systems. In the 1970s, structured programming became prevalent, leading to programs that were easier to develop and less likely to have errors.

In the 1960s a new kind of computer, the supercomputer, emerged. Expensive and oriented toward scientific computing, it was used in new centers in Europe, the United States, and Japan to offer scientists the opportunity to model physical systems. Since the late 1970s, most supercomputers have been parallel computers: many processors combine to work on different parts of a problem in parallel rather than in sequence.

In the 1950s and 1960s, the academic discipline of computer science emerged, a unique combination of engineering, applied mathematics, and technical craft. Whereas other sciences have a natural part of the world that is the object of their study, computer scientists study and expand technological creations. Purists argue that computer science, if it is to be worthy of the

name of science, should be only the study of algorithms, which are mathematically proven recipes for solving programming problems. Computer science included, from the 1950s, research into artificial intelligence, trying to create a combination of computer hardware and computer software that behaves as the human brain does. Research into artificial intelligence has led to advances in cognitive research.

In the 1960s, early networks endeavored to link computers together for communications. The Internet began with four nodes in 1969 as a creation of the Cold War and became a worldwide network of networks, forming a single whole. Tim Berners-Lee (1955–) invented the World Wide Web in 1991, a technology that made the Internet accessible to the masses. E-mail, file transfer, and other network technologies have allowed scientists to communicate more quickly and access supercomputing resources from a distance. Such technology has since revolutionized homes, workplaces, institutions, and daily life.

Computers are the great technological and scientific innovation of the second half of the twentieth century. Computers have made many scientific advances possible, from models of subatomic interactions to models of the birth and death of the universe. Computers have made possible space travel, advanced aircraft design, robotics, DNA sequencing, advances in nanotechnology, chaos theory modeling, and numerical analysis as well as the creation of atmospheric models, molecular dynamics, and models of proteins. As computers have become ubiquitous in daily life, the dominant trends in computing are ever more processing power and greater ease of use.

Artificial Intelligence

Artificial intelligence (AI) research involves the effort to create computer hardware and software that behave as humans do and actually think. Early computer pioneers, such as the mathematicians Alan Turing (1912–1954) and John von Neumann (1903–1957), intentionally developed electronic computers as the first step toward the creation of genuine thinking machines. In 1950, Turing created the Turing Test, a way of testing an intelligent machine. If a person could interrogate an intelligent machine via a teletype and at the end of the conversation not tell whether or not there was another person or a machine at the other end of the teletype, then that machine was intelligent. Although contemporary researchers no longer commonly accept the Turing Test as an absolute criterion, it serves as a good indicator of the goals of these early pioneers.

The term “artificial intelligence” was first coined in a two-month summer workshop at Dartmouth College in 1956, organized by the mathematicians Marvin Minsky (1927–) and John McCarthy (1927–). The first two decades of AI research were dominated by researchers at the Massachusetts Institute of Technology (MIT), Carnegie Tech (later renamed Carnegie Mellon University), Stanford, and International Business Machines (IBM). European efforts and Japanese efforts later became important. The second high-level computer language, called LISP (from “list processor”), was created specifically in 1958 by McCarthy at MIT for AI research.

The history of AI has been characterized by a series of theories that showed initial promise when applied to limited cases, leading to optimistic declarations that intelligent machines were just around the corner and to disappointment as the theories failed when applied to more difficult problems. In the early 1980s, expert systems showed promise. An expert system is created as a series of rules, with an inference engine,

► IBM'S DEEP BLUE

In May 1997, after six grueling games, chess world champion and grand master Garry Kasparov was defeated by a computer, the International Business Machines (IBM) Deep Blue. It was the first time a computer had ever achieved grand master status. Its victory in the six-game series not only shocked Kasparov but focused the media on the debate about the similarities between computers and humans and the nature of thought.

Some, such as pioneering roboticist Marvin Minsky, applauded IBM's creation. Minsky believed that Deep Blue's victory heralded an age where computers would one day dominate humankind. Kasparov also believed that Deep Blue was capable of thought; as he said, its abilities indicated something that "feels like thinking." Herbert Simon, Nobel laureate and designer of chess programs, also equated Deep Blue's methods with thought. The computer used two techniques: brute force (i.e., calculating the probability of each position's effectiveness) and avoidance (i.e., not analyzing moves with miniscule chances of success). Although Deep Blue could calculate 200 million positions per second, chess has 10^{120} positions; to avoid taking trillions of years per match, Deep Blue used avoidance.

Another distinguished group of commentators, however, argued against calling Deep Blue's functioning a product of autonomous thought. Deep Blue's chief architect, Feng-Hsiung Hsu, noted that it was incapable of intuition or feeling. Watching Deep Blue, Douglas Hofstadter, Pulitzer

Gary Kasparov plays against IBM's Deep Blue supercomputer in 1997. After losing two out of six games, with three drawn, the chess grand master was defeated, and for the first time ever a computer achieved grand master status. Kasparov believed Deep Blue could think, but its designers noted that it was more stupid than any human, being incapable of both intuition and feeling. (Stan Honda/AFP/Getty Images)

Prize-winning professor of computer science, revised his ideas about the definition of thought; it was not that Deep Blue thinks but rather that chess is not thinking, merely emotionless calculating. Hofstadter's conversion was similar to that of Jerry Fodor, who in the 1980s promoted the idea of the mind's information-processing nature, only to reject his own theory in 2000 in *The Mind Doesn't Work That Way*.

covering a narrow field of expertise. The first successful commercial expert system configured orders for Digital Computer Corporation computer systems. The promise of expert systems created a commercial expansion of the field, only to end in disappointment by the end of the 1980s as the expense and limitations of expert systems became apparent.

AI researchers developed a close relationship with cognitive science, the study of how humans think. One result of this relationship was the creation of neural networks, implemented in either hardware or software; these networks simulate the way the human brain uses neurons

to form patterns and change the relationships within those patterns. The concept of fuzzy logic also grew out of this relationship, allowing software to make decisions when input data remain uncertain and incomplete.

Robotics is related to AI in that many of the difficult problems in each field are similar. Industrial robots that perform limited tasks have become common, though general-purpose robots that can correctly perceive the natural world, through sight or other sensory means, and react to that sensory data remain visions of the future. Significant work at MIT's AI Lab in the 1990s has developed a different bottom-up approach

to robotics, using simple algorithms to create machines that move like insects.

Vision is a form of pattern recognition, and AI research eventually led to pattern recognition of optical characters, which became common by the 1990s. Effectively recognizing handwriting patterns also became possible in the 1990s. The solution of the related problem of voice recognition has resulted in simple commercial applications such as automated phone services and voice-activated word processing software.

In the popular realm, AI is often linked with ontological issues, that is, questions about the nature of being. Can machines that think be considered as having a consciousness? Movies such as Ridley Scott's *Bladerunner* (1982) and Steven Spielberg's *AI* (2001) explore the uncanny aspects of what appears to be human interaction with and potential replacement by artificial life-forms. Some robotics and artificial intelligence experts, such as inventor and author Ray Kurzweil, see themselves as ushering in a new higher species of life that ultimately will make biological humanity obsolete.

Computer programming does continue to astonish. In 1997, an IBM supercomputer called Big Blue defeated Garry Kasparov (1963–), the world chess champion, in a chess tournament, a feat once considered impossible. Many commercial computer games and video games have rudimentary AI algorithms to provide an artificial opponent for the human player. Japan's National Institute of Advanced Industrial Science and Technology created the Paro, a robotic seal-like pet that reacts and responds as if it is alive, providing a form of therapy for autistic children and the elderly. Computer programs can write poetry, diagnose illnesses, and serve as psychological therapists, yet some of the basic attributes of human thought have not and may never be mimicked by circuitry.

Internet

The Internet forms a global computer network interconnecting other computer networks, providing an unparalleled means of communication. The Advanced Research Projects Agency (ARPA) was formed in 1958 in response to the first artificial satellite, the Soviet Sputnik I, and the emerging space race. ARPA was an agency of the Pentagon, and the researchers at ARPA were given a generous mandate to develop innovative technologies. In 1962, a psychologist from the Massachusetts Institute of Technology's Lincoln Lab, J. C. R. Licklider (1915–1990), joined ARPA to take charge of the Information Processing Techniques Office (IPTO). In 1963 Licklider wrote a memo proposing an interactive network allowing people to communicate via computer. This project did not materialize. In 1966, Robert Taylor (1932–), then head of the IPTO, noted that he needed three different computer terminals to connect to three different machines in different locations around the nation. Taylor also recognized that universities working with the IPTO needed more computing resources. Instead of the government buying machines for each university, why not share machines? Taylor revitalized Licklider's idea, secured \$1 million in funding, and hired 29-year-old Larry Roberts (1937–) to direct the creation of ARPAnet.

Universities were reluctant to share their precious computing resources and were concerned about the processing load of a network. Wes Clark of Washington University of St. Louis proposed an Interface Message Processor (IMP), a separate smaller computer for each main computer on the network, that would handle the network communication. Another important idea came from Paul Baran (1926–), of the RAND Corporation, who had been concerned about the vulnerability

► WHITE HAT OR BLACK? HACKER SUBCULTURES

“White Hats” is the term that a group of computer science hobbyists from the Massachusetts Institute of Technology (MIT) adopted in the 1960s, identifying themselves with the good guys in old westerns. The Tech Model Railroad Club (TMRC) worked 30-hour-plus shifts to get its miniature railroads running smoothly. These were operated by telephone switch gears and vast primitive computers. The TMRC picked the locks to get in the building after hours and performed hacks, or programming shortcuts to improve their electronic systems and commands. The original term “hack” simply referred to a brilliant out-of-the-box prank that astonished the hacker’s peers; over time, hacks became associated with computers, since these scientists worked mainly with them.

White Hats gradually created the Hacker Ethic, which Steven Levy articulates in *Hackers: Heroes of the Computer Revolution* (1984). Besides the hacker’s passion for challenges, the Hacker Ethic holds that all information should be free. Authority is untrustworthy; rules simply obstruct development and hamper creativity. Some of information technology’s pivotal inventions grew from this code. In 1977, Steve Wozniak built the Apple I, precursor to current PCs, from scratch and originally just for fun. Richard Stallman founded the

Free Software Foundation (FSF) in 1982, a center of hacker activity dedicated to producing free high-quality software. The FSF tool kit helped Linus Torvald develop in 1991 the Linux operating system as freeware.

In contrast, in the computer community, Black Hats, or crackers, tend to be not just pranksters but vandals. Like White Hats, they believe in free information and often also in information theft. Unlike White Hats, their reasons are seldom altruistic; they defeat security systems for personal gain, to prove they are smarter, or to spite corporations. In an early example, John Draper was nicknamed “Cap’n Crunch” in 1971 for using whistles from Cap’n Crunch cereal boxes to produce an exact frequency to fool telephone switchboards and get free long-distance calls. Yet Draper’s curiosity was harmless compared to later movements such as warez, dedicated to breaking encryption codes used to protect copyrights for music, DVDs, and software. Besides helping the spread of hacking know-how, the Internet has spawned a new form of cracking: the creation of worms and viruses, such as the Code Red worm that caused \$2.6 billion in damages within 14 hours in 2001.

—Katie Gress

of the U.S. telephone communication system since 1960 but had yet to convince the telephone monopoly AT&T of the virtues of his ideas on distributed communications. He devised a scheme of breaking signals into blocks of information to be reassembled after reaching their destination. These blocks of information traveled through a distributed network, where each node, or communication point, could independently decide which path the block of information took to the next node. This allowed data to automatically flow around blockages in the network. Donald Davies (1924–2000) at the British National Physical Laboratory (NPL) independently developed a similar concept in 1965, which he termed packet-switching, each packet being a block of data. Although Baran was interested in a communications system that could continue to function during a nuclear war, ARPAnet

was purely a research tool, not a command-and-control system.

A small consulting firm in Cambridge, Massachusetts, Bolt, Beranek and Newman (BBN), got the contract to construct the IMP in December 1968. They decided that the IMP would only handle the routing, not the transmitted data content. As an analogy, the IMP looked only at the address on the envelope, not at the letter inside. Faculty and graduate students at the host universities created host-to-host protocols and software to enable the computers to understand each other. Because the machines did not know how to talk to each other as peers, the researchers wrote programs that fooled the computers into thinking they were talking to preexisting dumb terminals.

ARPAnet began with the installation of the first 900-pound IMP in the fall of 1969 at UCLA,

followed by three more nodes at the Stanford Research Institute (SRI), the University of California at Santa Barbara, and the University of Utah. The first message transmitted between UCLA and SRI was “L,” “O,” “G,” the first three letters of “LOGIN,” but then the system crashed. Initial bugs were overcome, and ARPAnet added an extra node every month in 1970. Improvements and new protocols quickly followed. Electronic mail, file transfer, and remote login became the dominant applications.

In 1981 the National Science Foundation (NSF) created the Computer Science Network (CSNET) to provide universities that did not have access to ARPAnet with their own network. In 1986, the NSF sponsored the NSFNET backbone to connect five supercomputing centers together. The backbone also connected ARPAnet and CSNET together. The idea of the Internet, a network of networks, became firmly entrenched. The open technical architecture of the Internet allowed numerous innovations to easily be grafted onto the whole. When ARPAnet was dismantled in 1990, the Internet was thriving at universities and technology-oriented companies. The NSF backbone was later dismantled when the NSF realized that commercial entities could keep the Internet running and growing on their own. The introduction in 1991 of the World Wide Web, developed by Tim Berners-Lee (1955–), took advantage of the modular architecture of the Internet and became widely successful. What began with four nodes in 1969 as a creation of the Cold War became a worldwide network of networks, forming a single whole. In early 2001, an estimated 120 million computers were connected to the Internet in every country of the world. As of 2009 the number of Internet users worldwide was estimated at 1.67 billion, approximately 1 out of every 4 people, and that number continues to increase.

Advances in Biotechnology

Biotechnology is a branch of technology that transforms humans and their environment through the manipulation of biological systems and the utilization of living organisms. Although the term was first introduced in 1919 by the Hungarian agricultural engineer Karl Ereky, human societies have long relied on the modification of biological agents to improve living conditions. A stellar example is the historical use of microorganisms in food and agricultural production. Yeast was used by the Sumerians and the Babylonians to make beer (ca. 6000 BC) and by the Egyptians to bake leavened bread (ca. 4000 BC). Microorganisms such as molds and lactic acid bacteria were also used to turn milk into cheese and yogurt.

Molecular biologists James Watson and Francis Crick discovered the structure of deoxyribonucleic acid (DNA), the molecular blueprint of all living organisms, in 1953. (Bettmann/Corbis)

► RECOMBINANT DNA TECHNOLOGY IN THE 1970S

In 1973 Stanley Cohen of Stanford University and Herbert Boyer of the University of California at San Francisco performed the first recombinant DNA experiment by introducing a plasmid into a strand of *E. Coli* using the restriction enzyme *EcoR1*. In the following year, the National Academy of Sciences convened a special committee chaired by Paul Berg to consider the health and safety aspects of this unprecedented type of biotechnology. The group published an open letter in *Science* in July 1974 calling attention to the potential hazards associated with the creation of novel types of infectious DNA elements. When the National Institutes of Health released the Guidelines on Research Involving Recombinant DNA Molecules in July 1976, the controversy surrounding this new laboratory technique unfolded in a series of public hearings before the Cambridge, Massachusetts, City Council over whether the city would allow recombinant DNA research to take place at Harvard and the Massachusetts Institute of Technology. While certain

prominent biologists joined the public and voiced serious concerns about this new experimental possibility, other scientists argued that although the biological properties of the recombinant DNA molecules could not be fully predicted, it would be equally unfair to expect that scientists have all the answers in advance for any kind of discoveries. The hearings must therefore be understood in terms of the sociopolitical context of the time, when the value and authority of science came under great suspicion as a result of the Vietnam War and emerging environmental and public health concerns about chemical pollution and radiation hazards.

Other fermentation processes were established in various parts of the ancient world, most notably in China. But it was really in the twentieth century, especially during its closing decades, that the involvement of public policy makers, heated discussions of ethical concerns in biomedicine and related professions, and the rising political valence of the pharmaceutical industry coalesced around the modern notion of biotechnology. The historical development of the various life sciences—such as genetics and microbiology—since the mid-nineteenth century undoubtedly contributed to the possible emergence of this modern biotechnology heavily rooted in genetic engineering and recombinant DNA technology. This process reached a crescendo in the 1970s and 1980s when developments in molecular biology and biochemistry significantly reoriented biotechnology from a professional to a policy category by shifting it toward a genetics-centered paradigm.

Already in 1866 the father of classical genetics, Gregor Mendel, delivered his laws of hered-

ity, which were rediscovered around the turn of the twentieth century by Hugo de Vries, Erich von Tschermak, and Carl Correns. In 1915, based on experiments using the fruit fly *Drosophila* as a model organism, Thomas H. Morgan reinterpreted Mendel's laws of inheritance in terms of his own chromosomal theory in *The Mechanism of Mendelian Heredity*. This new synthesis gradually led to the establishment of genetics as an isolated leading research field in biological science. Accompanied by the disciplinary emergence of molecular biology, classical genetics became molecular genetics by the 1960s after James Watson and Francis Crick published their seminal paper on the now famous double helix structure of DNA in 1953. Influenced by Watson and Crick, an increasing number of biologists attempted to reduce as many biological phenomena as possible down to the molecular level.

The statement of the central dogma, which posits that genetic information could proceed from a nucleic acid to a protein but not the other way around, and the deciphering of the genetic

code, which matches the genetic information on the nucleic-acid level to the genetic information on the protein level, secured a unique twentieth-century molecular vision of life. The concept provided a way to genetically engineer plants, organisms (such as viruses), and people. The possibilities for controlling or even eliminating genetic disorders and diseases turned many of the life sciences into a genetics-oriented body of knowledge by the early 1970s.

Before the second half of the twentieth century, biotechnology had primarily been associated with the selection, cultivation, and processing of naturally occurring organisms. The molecularization of biology defined its conception in a distinctly new light: starting in the 1970s, biotechnology has come to be understood as almost always involving some kind of genetic manipulation. Apart from Watson and Crick's discovery of the structure of DNA, another important event that contributed to this historical transformation was the formulation of a recombinant DNA technique by Stanley N. Cohen and Herbert Boyer in 1973. In their work, Cohen and Boyer excised a section of DNA from the plasmid of an *E. coli* bacterium and transferred it into the genetic material of another *E. coli*. This method allows bacteria to adopt the genetic material of other higher organisms, including humans, and therefore produce proteins of these higher organisms on demand. Popularly known as genetic engineering, this approach has defined the ground of modern biotechnology since the 1970s.

The early applications of this type of biotechnology included the development of genetically engineered drugs such as human insulin, approved by the U.S. Food and Drug Administration (FDA) in 1982; human growth hormone, approved by the FDA in 1985; and the hepatitis B vaccines, approved in 1986. Later, such medical applications of modern biotechnology would be called red biotechnology and expanded to include pharmacogenetics (the study of the relationship between an individual's genetic makeup and its influence on the body's response to drugs), genetic testing (including disease diagnosis, prenatal diagnostic screening, presymptomatic diagnosis, and, with the advent of DNA fingerprinting in 1984, forensic/identity testing), and

gene therapy (for treating or curing both genetic and acquired diseases), on top of the already mentioned pharmaceutical productions.

The term "green biotechnology" refers to the application of biotechnology to agricultural processes, such as improving yield from crops or altering the genetic nature of the crops themselves. For example, the first genetically engineered food product, the Flavr Savr tomatoes, gained FDA approval in 1994.

The term "white technology," also known as grey technology, refers to the application of modern biotechnology to industrial processes. A less popular term is "blue technology," which some people use to refer to the marine and aquatic applications of biotechnology. All of these modern biotechnological engineering processes are currently surrounded by intense political and ethical debates around the world.

Nanotechnology

Nanotechnology is an interdisciplinary scientific field that draws on physics, chemistry, biology, computer science, materials science, and engineering in its quest for understanding the world as it works on an atomic and near-atomic scale. It is a young scientific field with a history that goes back only a few decades. The first prophecy of an emerging field dates back to the Nobel laureate Richard Feynman's 1959 lecture "There's Plenty of Room at the Bottom." On the analogy of the completely new fields of physics that had

➤ ARE NANOBOTS POSSIBLE?

In his 1986 book *Engines of Creation*, Eric Drexler pictured the future of nanotechnology in terms of machines that could manipulate and build with individual atoms and even build copies of themselves. Drexler's futurist visions attracted much attention from the media and have been advanced from a multitude of sites on the Internet.

However, such views contrast with the reality of current research in nanotechnology. The American chemist and Nobel laureate Richard E. Smalley has raised two main arguments against the possibility of such machines: the fat finger problem and the sticky finger problem. In order to manipulate and build with individual atoms, the machine must not only be able to pick up atoms and insert them in the desired places but must also be able to control other existing atoms in the region. However, the manipulator arms are not irreducible in size but are themselves made of atoms, and they will therefore be too fat to be accommodated within regions of chemical reactions. Furthermore, the atoms of the manipulator arms may be imagined to control the atoms by adhesion, but then they will be too sticky to release the atoms in exactly the right spot.

—Hanne Andersen

been opened at the beginning of the twentieth century by the investigation of properties of matter at very low temperatures and at very high pressures, Feynman prophesized that a similarly new field would be that of the manipulation and control of things on a very small scale.

Feynman's talk foreshadowed two current areas of interest: the investigation of the special laws that will apply to material on the nanoscale and the manipulation and control of the arrangement of things on the atomic scale. Thus, nanoscientists work at understanding what can happen and what can be done at the nanoscale, which forms the borderland between individual atoms and molecules and the macroworld of bulk material. At this mesoscale between the purely atomic and purely macroscopic bulk level, a new blend of classical physics and quantum physics has to be developed. Some of the physical and

chemical subdisciplines that form important parts of nanoscience are areas such as cluster physics, which studies the gradual development of collective phenomena that characterize a bulk solid, and supramolecular chemistry, which focuses on the noncovalent bonding interactions of molecules. Another important interest in nanoscience is to look at natural structures in biology in order to emulate some of biology's nanoscale engineering.

Technological advances are also an integral part of nanoscience. One very important invention for the study of matter at the nanoscale is the scanning tunneling microscope (STM) that images individual atoms by tracking the changes in an electric current as an ultrasharp tip is swept over a surface. The STM was invented in 1981 by two IBM physicists, Gerd Binnig and Heinrich Rohrer, who received the 1986 Nobel Prize in Physics for this invention. A few years later, two other International Business Machine (IBM) scientists, Donald Eigler and Erhard Schweizer, managed to use the tip of the STM to move atoms around, and the image of the letters "IBM" written with individual xenon atoms on a nickel surface became an icon for atomic manipulation. Another nanotechnology breakthrough has been the discovery of fullerenes, which are carbon molecules that form either hollow spheres (buckminsterfullerene, or buckyballs for short) or cylinders (carbon nanotubes). Carbon nanotubes have very interesting properties. For example, they are very good conductors of heat and electricity, and they have a very high tensile strength. They have therefore given rise to much excitement as well as speculations about the many exciting applications that are expected to be developed once their synthesis can be fully controlled.

During the 1990s the first journals devoted exclusively to nanotechnology emerged, and by the beginning of the twenty-first century degree programs dedicated to nanotechnology were offered at many universities. As the field advanced, the potential contributions of nanotechnology to future economic growth brought increasing government attention, and large-scale initiatives were established, such as the U.S. National Nanotechnology Initiative in 2001 and the European Union Nanotechnology Action Plan in 2004.

Eric Drexler, author of *Engines of Creation* (1986), a look at the future of nanotechnology, with a large scale model of “immune machines” that would patrol the human body. (Ed Kashi/Corbis)

One of the prophets who has been very visible in the media coverage of nanotechnology is the American engineer Eric Drexler, whose popular book *Engines of Creation* (1986) introduced a wide audience to some of the issues relating to nanotechnology and its use in society. In this book Drexler described machines that manipulate and build with individual atoms, projecting that such assemblers would eventually be able to make virtually anything from common materials and without human labor. According to this vision, nanotechnology would remake our machines, our lives, our economy, and our world, for better or for worse. Thus, Drexler also imagined that nanotechnology could produce dangerous replicators that were so tough, so small, and so rapid in growth that the resulting so-called grey goo might obliterate all living organisms on earth. This scare vision reached the popular press and public culture, such as in the form of best-selling author Michael Crichton’s 2002 thriller *Prey* in which a scientist combats swarms of predatory nanobots. However, Drexler’s vision of building things atom by atom and molecule by molecule has so far remained a futurist’s dream.

Even if replicators prove impossible, nanotechnology will undoubtedly lead to enormous technological advances, including, for example, new recording media with a million-fold increase in storage capacity; new materials with excep-

tional combinations of strength, toughness, and lightness; and the development of personalized medical drugs.

Industrial Robots

The idea of robots has long flourished in the human imagination. In the eighteenth and nineteenth centuries in Europe and Asia, popular clockwork automatons played chess, served tea, gave musical performances, and in the case of Jacques de Vaucanson’s “Digesting Duck” appeared to drink, eat real grains, and defecate. Automata also appeared in early science fiction, such as the dime novel series *The Steam Man of the Prairies*, which debuted in the United States just after the U.S. Civil War. In 1920 the Czech novelist and playwright Karel Capek came up with the word “robot” from the Czech word for “slave” for such machines in his play “Rossum’s Universal Robots.” Yet at the opening of the twenty-first century, the grand goals of roboticians and science fiction fantasists—the creation of autonomous artificial beings that might do all the hard labor and ensure a leisure world for humans—had not been achieved. Robots have been designed for useful tasks: assisting in surgery, conducting remote exploration in oceans and on distant planets, serving as therapeutic pets, cleaning sewers, vacuuming rooms, and disarming roadside bombs. The most singular achievement in robotics, however, is the most prosaic: the post-World War II development of the industrial robot.

Inventor George C. Devol patented his industrial robot, the Unimate, in 1954, and talked

> ROBOCUP

In 1993 Japanese robotics experts Hiroaki Kitano, Minoru Asada, and Yasuo Kuniyoshi attended an American Association for Artificial Intelligence competition that involved robots performing tasks such as lifting paper cups from tables. Concluding that robot developers could use a more dramatic vehicle, the three roboticists eventually came up with the idea of a Robot World Cup soccer competition, or RoboCup for short. The first tournament was held in Nagoya in 1997 and included 333 teams from 31 countries. The 2005 tournament in Osaka drew as many as 36,000 spectators a day to its exhibition halls. Various divisions have developed, such as a Four Legged League now dominated by Sony Aibo robo-dogs; a RoboCup junior league that drew student teams from 18 countries in 2005; a Middle Sized League that permits teams of rapid-wheeled robots; and a RoboCup Rescue division that involves sending rescue robots through simulated wreckage. Teams in the humanoid division compete for the coveted Louis Vuitton-designed crystal Humanoid Cup. The ultimate goal—much like that of the IBM team that built the computer Deep Blue that first defeated chess grand master Gary Kasparov in 1997—is to spur research that may lead by the year 2050 to the development of a robot team

Competitors in the Humanoid Division face off at RoboCup 2006 in Bremen, Germany. (Niels Heidenreich)

capable of beating the world's reigning human World Cup team.

—Fred Nadis

up his idea to businessman and scientist Joseph F. Engleberger at a 1956 cocktail party. They sold their first robots to General Motors in 1961 and founded Unimation Incorporated in 1962. The Unimate was a smart tool, a flexible hydraulic arm that could swivel, rotate, slide, bend, or grasp at various joints (each such opportunity known as a degree of freedom), providing remarkable mobility, dexterity, and strength. The first models could lift 100 pounds and could be programmed to perform such tasks as welding, operating machine lathes, and applying spray paint. All the Unimate's movements were easily programmed without computer commands. An operator simply pushed a record button and guided the arm through its proper movements, each step of which could be refined and stored on a magnetic drum. These fixed-position robot arms were soon joined by gantry robots that

could move on overhead rails; video cameras and other sensors were also introduced to provide input for guiding mechanisms.

Unimate and Kawasaki Motors teamed in Japan in 1968 to create the Kawasaki Unimate 2000. At first relying on joint ventures with manufacturers such as Tralfa in Norway and VFW in West Germany, other Japanese automobile, electronics, and steel manufacturers began to develop and adapt robots as Japanese industry turned to a steel-collar labor force. One decade later, 10,000 industrial robots a year were being sold in Japan. Aided by research at MIT and Stanford, in 1978 Unimation developed its Programmable Universal Machine for Assembly (PUMA), allowing for more intricate movements and sensor input in its guidance systems. In 1981 Sankyo Seiki began manufacturing a generation of lighter, swifter robot arms with less vertical flexibility

yet ideal for assembly line-style electronics manufacture. The new arm was called the Selective Compliant Assembly Robot Arm (SCARA). New two-armed robots were developed for the interior assembly of automobiles as well. In 1987 approximately 116,000 industrial robots operated in Japan, compared to 25,000 in the United States, 12,400 in West Germany, and 5,300 in France. In 1987 in Japan, while 40 percent of industrial robots worked in the automobile industry, the remainder were used in electronics and other assembly plants.

Industry elsewhere had been receptive to the use of robots but cautious regarding labor and safety issues. In 1981 in a much-publicized incident, the first robot murder occurred at a Kawasaki plant in Japan, when a robot pushed a worker into a grinder and killed him. Yet by 1980, Japan's manufacturing success led a trend toward robots in Western nations as well. The ensuing boom ended in a late 1980s bust when instant profits outside of the automobile industry were not realized and many robot manufacturers folded. Robots have since become an important focus for research and development and manufacture worldwide.

Between 1994 and 2000 the number of businesses in the Alliance of Manufacturers and Exporters of Canada relying on robots, for example, increased from 8 percent to 22 percent. In 2005 there were 158,000 robots installed in

the United States and a little over \$1 billion in new sales in North America. That same year, the People's Republic of China employed 11,557 robots. Following Japan, as of 2006 Italy had the highest concentration of robots to workers in its automotive industry. The worldwide market for industrial robots in 2006 was estimated at \$6 billion. Businesses such as Microsoft have begun to invest in robotics research, particularly in software systems, while Japanese automobile firms such as Honda and Toyota continue to research mobile humanoid robots for domestic use. While industrial uses will continue to multiply, the home and world outside the factory remain the new frontiers for robot developers.

■ Introduction: Science, Technology, and Culture

Langdon Winner's study *Autonomous Technology: Technics-out-of-Control as a Theme in Political Thought* (1978) addressed the central fear that science and technology are unstoppable forces, revolutionizing life and offering utopian promises but more often than not providing dystopian consequences. In this sense, there is no study more important than that of the social and cultural consequences of science and technology, an interest that has gathered among scholars in recent decades largely with the hopes of establishing that sci-

ence and technology are social processes that indeed can and should be controlled for the social and environmental good. Concepts such as Moore's Law (1965) that so far has accurately predicted that computing technology will be able to double its efficiency every two years, breakthroughs in genetic engineering, and pioneering efforts in nanotechnology ensure that science and technology will continue to revolutionize daily life. How these forces can be channeled to serve rational ends and the greater good remains of critical importance. In philosophy,

art, and literature, intellectuals and artists continue to explore the ramifications and possibilities of scientific research and technological development.

Critiques of the Idea of Progress

While isolated writers have spoken of human progress throughout history, it was only among West Europeans in the seventeenth century that a belief in such progress became widespread. European Enlightenment thinkers of that age argued that advances in scientific understanding would support progress not just in technology but also in economics, politics, and culture. The political and economic dominance of industrialized states during the nineteenth and early twentieth centuries caused societies across the world to embrace for the first time the notion that their well-being depended on the pursuit of change,

now defined as progress. Indeed, before the Enlightenment the word “progress” tended simply to imply “more.” Today, the word “progress” implies the achievement of better societal outcomes.

The horrors of the two world wars and the Great Depression of the 1930s inevitably blunted confidence in human progress and its link to technological advances in the first half of the twentieth century. Thereafter, confidence in progress rebounded but waned again in the closing decades of the century. Various problems of contemporary life—environmental deterioration, the threat of nuclear war, refugees, cultural dislocation, and, more recently, global warming—comprise one important source of that pessimism. Science and progress no longer seemed inevitably linked. The failure of socialist countries to achieve superior societal outcomes was another source of disillusionment for many intellectuals. Social programs in the West and thus by implication social science itself have likewise failed to solve social problems. Last but not least, developments in philosophy were interpreted in a way that encouraged pessimism.

To define what is better is an ethical challenge, and modern philosophy suggests that there is no one correct method of ethical evaluation. For many, especially but not exclusively writers on the postmodern condition, the notion of human progress thus appeared meaningless. Alternatively, though, one might argue that widespread consensus exists regarding at least some sorts of progress: eliminating hunger, expanding personal security, and curing disease.

Even if humanity could agree on what progress might mean, it must be able to successfully achieve this. Developments in epistemology and rhetoric as well as in literary theory and postmodern thought have suggested that rational thought does not govern human affairs. Humans send mixed messages, reflect a host of psychological and sociocultural biases, utilize necessarily ambiguous language, and make decisions on the basis of emotion rather than reason. Science and technology themselves have hardly been immune to these influences. While there is scholarly consensus that such limits to rationality are real, there is heated debate about their importance and thus whether the (fallible) pur-

➤ NEO-LUDDISM

Drawing its name from the Luddites or artisans who sought to destroy power looms in the early nineteenth century to protect skilled artisans' welfare, Neo-Luddism includes various recent movements opposed to notions of progress in modern society. Neo-Luddites, typically labeled that by others, are opposed to technological developments and their alleged corrupting influence on human values and quality of life in the broadest scale. Many of these Neo-Luddites are content to avoid as much as possible the use of technology. However, a more extreme ideology of anarcho-primitivism blames science and technology for creating and perpetuating social stratification, increased state control over society, unequal distribution of wealth, and environmental degradation. An even more extreme variant of these would be environmental activists and radicals, such as the Earth Liberation Front, opposed to technology for its role in the destruction of the environment and in the abuse of animals. Such radical groups have often taken part in the active destruction of auto sales lots and all their stock and breaking into and liberating laboratory animals.

—Abraham O. Mendoza

suit of progress is possible. Moreover, even if humans were incapable of purposely pursuing progress, they might still achieve this in a gradual evolutionary sense by recognizing and maintaining progressive outcomes when these occur by chance.

If human rationality can be rescued, it might nevertheless be thwarted by the complexity of the contemporary world. Scholarship is fragmented into thousands of specializations, while the complex problems faced by humanity such as global warming or inner-city poverty require integration of numerous specialized insights. The social and natural worlds function as complex systems, and even the most rational of plans may produce unforeseen negative consequences. Indeed, humanity may not even be able to recognize correctly a progressive or regressive outcome. It may, for example, applaud economic growth without recognizing the environmental or cultural dislocation associated with it. Again, while the problem of complexity is real, scholars debate the degree to which strategies for integrating knowledge can alleviate this. While an uncritical faith in science or reason as autonomous forces leading inevitably to progress is no longer tenable, the Enlightenment thinkers' endorsement of the scientific method and goals of social improvement remain admirable.

Science Wars

Prior to the 1960s, sociological and historical studies of science tended to be internalist accounts that examined the development of science in terms of problem solving, the jettisoning of failed theories, and the continuous develop-

ment of scientific expertise. The publication of Thomas Kuhn's *The Structure of Scientific Revolutions* (1962), however, provided an alternate method of thinking about science. Kuhn argued that social factors and not just pure logic often had an important influence on the debates that led to a new scientific consensus and a new conceptual model—or paradigm—for a field. Since Kuhn, scholars have continued to explore the influence of social factors on scientific and technological research. Sociologists who adhered to what was called the strong program in science such as David Bloor, Harry Collins, Steve Woolgar, Bruno Latour, and others encouraged the position that all knowledge is socially constructed. Their relativism tended to be methodological; that is, they proposed symmetry in their research as a means for investigating the social factors behind both winning and losing sides of scientific controversies. Yet this position was easily transformed into the more dubious critique that scientific knowledge is ultimately a language game, hopelessly mired in ideology, with little claim to objective truth. As the strong program became popular in the 1970s and 1980s and was seized upon by postmodern literary critics, defenders of scientific objectivity publicly condemned the entire school of thought as well as the new academic programs in science and technology studies that encouraged such scholarship.

In many ways these late twentieth-century science wars replayed earlier debates. For example, in the late nineteenth century in England, Matthew Arnold and T. H. Huxley debated the cultural primacy of science and the humanities. Huxley, a naturalist, politely nodded to the importance of the humanities but championed a scientific education. He pointed out that most of the romantic critics of science were largely "ignorant of the first principles of scientific education." In Arnold's lecture "Science and Culture" delivered at Cambridge in 1882, the poet reduced science to a simple cataloging of material facts while hailing the humanities for providing a moral guide and harboring "the best which has been thought and said in the world." These issues were revisited with the publication in 1959 of C. P. Snow's Cambridge lecture "The Two Cultures and the Scientific Revolution." Snow, a

► THOMAS KUHN'S IMPACT

Thomas Samuel Kuhn (1922–1996) is one of the most widely read philosophers of science of the twentieth century. In his principal work *The Structure of Scientific Revolutions* (1962), Kuhn criticized the received view of a cumulative development of science and claimed instead that scientific fields periodically underwent revolutions, or paradigm shifts. The new paradigm will then map out anew acceptable research problems, potentially acceptable solutions to these problems, and even which phenomena and entities can be assumed to exist. The new paradigm in a field may therefore be so different from the old one that it cannot be seen simply as an extension or a refinement. Kuhn termed this relation incommensurability.

Kuhn's phase model presupposes that the members of a scientific community periodically reach a new consensus on various fundamentals. Distinction can therefore be made between a mature science in which shared paradigms have been developed and a preparadigmatic science that is characterized by a variety of competing schools of thought. Kuhn claimed that the various scientific disciplines have reached maturity at different times in history.

Kuhn opened up new ways of thinking about science as a social enterprise. His incommensurability thesis implied that scientists cannot decide between competing paradigms solely on the basis of reason, argument, and evidence; other factors may also play important roles. This called for new kinds of studies that examined how social, cultural, political, and psychological factors external to science could influence the outcome of scientific debates. In this way, Kuhn helped engender the theory of the social construction of knowledge

and of scientific knowledge. The most extreme adherents of this constructivist movement claimed that the influence of these external factors was the dominant factor for the development of science, but these were views that were very far from what Kuhn had himself intended. Nevertheless, Kuhn has often been denounced as a relativist and irrationalist, and in the late 1990s scientists battling postmodern relativism in the so-called Science Wars viewed Kuhn as one of the instigators of the antiscientific views they were fighting against.

Kuhn's impact goes much further than his influence on science studies. His distinction between mature and preparadigmatic science has been discussed by scientists in many fields seeking the mantle of maturity. By the same token, his incommensurability thesis has been used by adherents of all sorts of alternative worldviews to deflect criticism raised by opponents. Above all, the notion of paradigm shifts has passed into everyday speech and is used to denote shifts in beliefs or organizations of all types.

scientist and novelist, announced that the widening divide between science and the humanities posed a danger. From a Cold War perspective, the hostility to science among Western literary intellectuals and educators could only aid the Soviet Union in its efforts to spread its empire by lending expertise and industrializing the poorer nations of the Third World.

The science wars of the late 1980s and 1990s also played out the debate over the cultural pri-

macy of the humanities or the hard sciences. Defenders of science angrily attacked the ideological critiques of science offered by cultural studies scholars and sociologists. The first major salvo in this battle was the publication of Norman Levitt's and Paul Gross's *Higher Superstition: The Academic Left and Its Quarrels with Science* (1994), a critical examination of the work of cultural studies scholars who embraced social constructivism in their critique of science and

its ideological dimensions. Shortly after this work appeared, New York University physicist Alan Sokal continued the demolition of the reputation of social constructivism when he penned a parody of such scholarship titled "Transgressing the Boundaries: Towards a Transformative Hermeneutics of Quantum Gravity." Much to his amusement, the journal *Social Text* accepted the article in full for its "Science Wars" issue in 1996 even though the article was loaded with dubious scientific assertions and postmodern buzzwords. Shortly after, he exposed his ploy, and news of the Sokal Hoax led to the public humiliation in various journals of postmodernists and their pretensions to the moral and intellectual high ground.

While the Sokal Hoax largely silenced the culture studies camp's more dubious pronouncements on science, the serious sociological and historical study of science has continued. Stephen Jay Gould, the evolutionary biologist and essayist and a friend of Sokal's, was bothered by the notion that the hoax once again asserted the primacy of science over the humanities. Afterward, he defended "the vast bulk of scholarly work in the social analysis of science as not only important and respectable, but as immensely salutary for scientists who rarely think enough about the historical background and immediate social contexts of their research." Gould's posthumous work *The Hedgehog, the Fox, and the Magister's Pox: Mending the Gap between Science and the Humanities* (2003) returned to the study of the two cultures problem. Like Snow, Gould argued that both camps had value and that the reductive project of claiming science preeminent or urging the humanities to remain silent about science was counterproductive.

Imperialist Anthropology Examined

As the comparative study of human society and culture, the field of sociocultural anthropology is a relatively young discipline. Tracing its roots to the latter half of the nineteenth century in both Europe and North America, the field has distinguished itself on two different counts. First, sociocultural anthropology developed with a focus on the peoples of the non-Western, non-industrialized world. Second, anthropologists retain a distinctive methodology based on the belief that an extended period of social and cultural immersion within a respective community of study yields a unique form of knowledge. Referred to as participant observation, this method of inquiry allows the anthropologist to interpret and contextualize in such great depth and detail that meaning can be grasped and conveyed.

The development of sociocultural anthropology is intricately tied to a history of Western imperialism. In North America, the field arose in the context of America's westward expansion. As the U.S. government moved to fulfill its self-professed Manifest Destiny, it inevitably came into contact and conflict with the Native American peoples already long present on the continent. The problematic nature of this encounter led to government sponsorship and the eventual professionalization of the fledgling discipline. Through the Smithsonian's Bureau of Ethnology (established in 1879) and the Department of the Interior's Office of Indian Affairs, the U.S. government supported anthropological research in an effort to effectively settle, administer, and assimilate the various Native American groups.

► ANTHROPOLOGISTS AND THE WAR ON TERROR

In late 2007, the question of imperial anthropology surfaced once again, this time in the context of America's war on terror. The debate's resurgence was sparked by the introduction of the U.S. Army's Human Terrain System (HTS). The program deploys anthropologists and other social scientists to Iraq and Afghanistan in support of the military's efforts there. Anthropologists working in this capacity research indigenous social structures, local forms of authority, and grassroots networks, among other things. The information collected by the anthropologists is fed back to the military's decision-making process. According to the U.S. Army, ethnographic intelligence allows its forces to undertake counterinsurgency more effectively, thereby saving lives in the process. Proponents of the program claim that HTS contributes to a more secure world and builds cross-cultural understanding.

Despite its wide support within military circles, HTS has provoked significant criticism from most anthropologists. These critics assert that by con-

doning or participating in the program, anthropologists breach their discipline's ethical guidelines. In particular, they argue that it is impossible for these anthropologists to provide full disclosure to their informants, that their responsibilities toward the U.S. military conflict with their obligations toward the persons they study, and that in a war zone it is virtually impossible to acquire voluntary informed consent from research subjects. Furthermore, since such anthropological research may help to identify military targets, it violates the discipline's code against harming the subjects of one's study. Finally, the critics of HTS argue that the program promotes the association of anthropology with the U.S. military and thus creates difficulties and risks for the majority of non-HTS anthropologists. For all of these reasons, in late 2007 the Executive Board of the American Anthropological Association, the world's largest professional anthropology body, described HTS as an "unacceptable application of anthropological expertise."

—John T. Friedman

On the other side of the Atlantic, a different set of imperial contexts helped drive the new discipline. In Europe, late colonialism (ca. 1870–1960) offered opportunities for early anthropologists to further their careers through research in Africa, Asia, and Melanesia. In this respect, the British empire was most formative; however, anthropologists also worked in the Belgian, French, and Dutch colonies.

By the mid-twentieth century, sociocultural anthropology had taken its place as an established discipline among the social sciences. Although the period of formal colonialism was drawing to a close, a number of other imperial projects were garnering support from some corners of the discipline. In particular, the apartheid regimes in South Africa and Namibia drew on anthropology to both justify and enforce their system of racial oppression; likewise, during the Cold War the U.S. Army recruited anthropologists for its Project Camelot (1964–1965), a covert research program that aimed to utilize social scientific knowledge for counterrevolutionary ends, especially in Latin America. It was precisely

within these circumstances that a much more critical and self-reflective anthropology began to emerge.

The first concerted attempts to confront a so-called imperial anthropology took shape during the late 1960s and 1970s. For example, in 1968 anthropologist Kathleen Gough opened up a vociferous debate when she charged her discipline with failing to acknowledge the existence of Western imperialism and for ignoring the effects of such a system on the peoples and places anthropologists tended to study. Similarly, in 1973 Talal Asad and his colleagues reflected critically on the relationship between anthropology and colonialism. This project generated a view that was both complex and ambiguous. In the end, this group of studies showed that colonialism had a greater impact on anthropology than anthropology had on colonialism. Finally, in 1978 Edward Said, notably in his work *Orientalism* (1978), criticized Western scholarship more generally for essentializing and subordinating other cultures, an argument that further fueled, albeit indirectly, a notion of an imperial anthropology.

By the late 1980s and early 1990s, these initial attempts to examine the relationship between anthropology and imperial power were eclipsed by a much deeper and altogether more challenging critique. This new postmodern critique sent anthropology into deep crisis. If, as the postmodernists argued, there is no single, objective account of sociocultural reality, then ethnographic accounts must lack intellectual authority. Scholars such as James Clifford, George Marcus, and Michael Fisher thus led the debate by questioning anthropology's ability to represent culture and society. The imperialist question had surfaced once again but this time in a more intellectual vein. Postmodernism forced anthropology to scrutinize its methods, its claims, and its underlying assumptions. In response, some anthropologists experimented with their research methods and writing styles. Such innovation has granted more space for anthropology's subjects to represent themselves.

In the new millennium, it is now clear that sociocultural anthropology not only survived its crisis of authority but also was strengthened by it. The postmodern turn in anthropology does retain its strong critics. However, despite its legitimate shortcomings, the shift in thinking that accompanied its rise was indeed an important and much-needed corrective. As of the early twenty-first century, anthropology's imperial tendencies and history are well understood. In particular, anthropologists are more aware of the complex relationship between anthropology and power: anthropologists study power, the discipline is shaped by power, and anthropology exerts power in its own right.

Gender, Science, and Technology

Whereas a distinction between sex and gender was almost nonexistent in the late nineteenth century, the notion of gender as a social category distinct from biological sex became common in scientific and medical discourses as well as in everyday lexicon by the closing decades of the twentieth century. The period between the 1890s and the 1990s witnessed a dramatic transformation in which biological determinism slowly gave way to social constructionism in accounting for the patterns, behaviors, and roles of women and men in society. This historical transformation reflects both the changing sociopolitical pressures and, perhaps more importantly, the dominant trends in science, medicine, and technology as they have evolved over the past 100 years.

The influence of feminism in particular has tremendously reshaped science, medicine, and technology in terms of both their professional orientation and cultural consequences. By the 1880s and 1890s, the nineteenth-century women's movement had propelled women into higher education across Europe and North America. New Women such as Margaret Sanger toured the world to promote birth control methods in the first few decades of the twentieth century. The rebirth of feminism in the 1960s, reaching its peak and joined by the increasingly visible gay and lesbian movement in the 1970s, further pushed issues of gender and sexuality to the forefront of politics.

Gradually, feminism has not only opened up many fields in the sciences to women but has also fundamentally reoriented the theoretical underpinnings and practices of research. In medicine, for instance, it is now routine for clinical trials to take into consideration the physiological differences between men and women. In computer science, software engineers have adopted, however unconsciously, an epistemological standpoint defined around gender in the practice of programming and for rethinking the human-interface problems resulting from people's growing reliance on computers. The increasing female

WOMEN AND THE PHYSICAL SCIENCES

Women have historically participated in scientific, mathematical, and technological developments, but they have not always been recognized for their contributions. Two factors changed this: women's movements and professionalization. In the middle to late nineteenth century, the suffrage movement gained momentum in countries such as the United States and Great Britain. At the same time, women gained access to education and training in scientific fields thanks to the rise in new women's colleges and traditional universities admitting women in Western countries.

While the number of women college graduates increased through the twentieth century, areas of study often were limited to those deemed appropriate for women. In the physical sciences, women were often relegated to assistant positions, prevented from presenting research findings at professional conferences, and received limited funding for their research projects and less pay than male colleagues. With rare exceptions, such as the work of Nobel Prize winning scientists Marie Curie (1904 in physics, 1911 in chemistry) and Maria Goeppert Mayer (1964 in physics), women's contributions to advancements in scientific knowledge went unrecognized.

Following the renewed women's movements of the 1960s and 1970s, women scientists have

British scientist Rosalind Franklin aided in the discovery of the molecular structure of DNA. Her contribution was not fully acknowledged when Americans Francis Crick and James Watson were awarded the Nobel Prize for the discovery in 1962. (Courtesy Jenifer Glynn/National Institutes of Health)

women's enrollment, participation, and recognition in science.

—Heidi Allene Henrickson

steadily increased in number. According to studies by the National Science Foundation, in the United States the number of female physical science undergraduates increased from 14 percent to 46 percent between 1966 to 2007. According to studies by the European Commission, the total number of women professors of natural science in Europe increased 23 percent between 1999 and 2002. These statistics indicate recent rapid changes due in part to European Commission efforts to bolster

participation in science, the health care profession, engineering, and other fields associated with technological research and development reveals the impact of feminism, which altered both the social expressions of the relationship between the sexes over time and, ultimately, the cultural conceptualization of gender itself.

Yet the historical process of separating out gender from sex owes as much to internal developments in science as to sociopolitical influences. Reflecting the ascending cultural authority of the mental health profession over the course of the twentieth century, the conceptual distinction between gender and sex first appeared in the medial literature during the 1950s. In an article published in 1955, the Johns Hopkins University medical psychologist John Money used the term “gender role” for “all those things that a

person says or does to disclose himself or herself as having the status of boy or man, girl or woman” and the term “gender” to refer to “outlook, demeanor, and orientation.” In 1964, building on Money’s vocabulary, the psychoanalyst Robert Stoller, working with his colleague Ralph Greenson at the UCLA Medical School, coined the concept of gender identity to indicate more directly one’s core sense of self as “being a member of a particular sex.” If by “gender role” Money referred to socially prescribed behavior patterns, Stoller and Greenson adopted the term “gender identity” to identify another layer of gender that is strictly psychological. In fact, they further differentiated gender identity from sexual identity, which encompasses one’s sexual desire and erotic drive, and thus distinguished gender from sexuality accordingly.

Whereas concepts of sex, gender, and sexuality were undistinguishable in the nineteenth century, the language of psychology now provides medical and scientific authorities as well as the lay public with sufficient working definitions for setting them apart. The second-wave feminists would quickly endorse and wield this novel language of gender in the 1960s to challenge discussions of sex roles in strict biology-as-destiny terms, a legacy that continues to the present day.

Bioethic Debates

Fears about science gone awry are not new. J. W. Goethe's *Faust* (1790) and Mary Shelley's *Frankenstein* (1818) both reflected an ongoing cultural fascination with the possibility of creating or reshaping life through scientific intervention. As breakthroughs occur in science, technology, and medicine, the potential to generate human organs, offer brain implants, and clone and alter life in general inspires both public fascination and fear. Alongside medical and scientific advancement has come new possibilities and, inevitably, public reflection and ethical debate.

The discipline of bioethics is traceable through its institutionalization in the late 1960s, when important developments in science and

ETHICS AND DEVELOPMENTS IN STEM-CELL RESEARCH

The potential medical benefits of the research of stem cells (unspecialized human cells with the potential to grow into different cell types) are well known. They offer potential therapeutic benefits for treatment of heart disease, diabetes, and other diseases. Such research has been controversial because of the process by which such cells were gathered. Because embryonic stem cells were derived from early fetal stem cells, often from aborted fetal tissues, this research compelled controversy. Some application-related concerns still exist about the potential for human cloning and its associated ethical challenges. However, new research obviates some of these older ethical debates. Recent discoveries regarding the cloning of adult stem cells promise new therapeutic uses. Also, cell transdifferentiation (in which adult stem cells can be induced to develop into cells for organs or tissues other than those from which they were derived) may someday enable other uses. The possibilities unearthed through this kind of research still compel important social conversation.

—Mark Robinson

medicine emerged following the research investments of World War II. New developments in genetics, transplantation, and life-prolonging technologies compelled intensified discussion during the heightened political climate of the 1960s. In addition to religiously informed debate, much of the field extends from academic disciplines, with philosophers, social scientists, and physicians dominating bioethical debate in recent history. Additionally, there has been more attention to non-Western ethics traditions in contrast to historically (and presently) Western-dominated bioethics. As a result of anthropological and feminist critiques, multicultural, global, and feminist-informed ethics have come to the fore.

Even within the West, debates on issues such as abortion, stem-cell research, genetic testing, and assisted suicide often index a multitude of perspectives, whether explicitly religious or more secular in basis. For example, in response to the

possibility of human cloning, Christian ethicists offered biblical arguments about human nature. Similarly, debates about the 1973 ruling over abortion rights (*Roe v. Wade*) and the very public 2004 assisted suicide case of Terry Shiavo often focused upon theological conceptions about how life is constituted.

So-called secularist bioethical debate takes up the above issues via philosophical deliberation and appeals to rationality, reason, and a commitment to liberal ideals such as autonomy, democracy, and equality. This approach takes ethics as an extension of Western philosophy rather than a commitment to particular religious worldviews. In an attempt to create a more universal ethical framework, secular approaches tend to dominate global bioethics discussions especially in reference to human rights. For example, female genital cutting (sometimes referred to as female genital mutilation) is one practice that cannot be easily addressed in bioethics bereft of adequate attention to the cultural and religious contexts of the practice.

While the secular rights-based approach to ethics is often contrasted against religious approaches, this binary is much more complicated. Religious perspectives can also take up a rights-centered discourse. For example, Catholic ethicists often argue that unborn children and the severely disabled possess a right to life. An example of this stance is found in the Vatican's 1980 "Declaration on Euthanasia."

Secular bioethicists' concern about universal human equality maps out specific areas in which to examine genetics research. The relationship between genetics and adaptability, intelligence, and behavior means that the prospects of genetic engineering or neurological enhancement compel fears of something akin to a modern eugenics movement. Concerns about biological determinism also accompany the use of genetic screening. The passage in the United States in 1972 of the National Sickle Cell Anemia Control Act, for example, brought about discussions regarding the ethics of genetic screening. Theologian-turned-bioethicist John Fletcher echoed other ethicists in his argument, questioning therapies that sought to perfect humankind. In reflection about the possibility of human enhancement, secularist approaches often point

to the ethical problems related to diminished autonomy or inequality; in contrast, the religiously derived approaches focus on the problem of altering nature, or God's perceived handiwork.

As Western bioethics matured, several forms or modes of debate became institutionalized. One mode of ethical engagement, principlism, relies on deductivism and a strong commitment to specific ethical principles. With its commitment to respect for persons, beneficence, and justice, principlism often underlies many models of decision making and deliberation in the West. Principlism in bioethics took shape in the United States after the Belmont Report (commissioned by the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research) in 1979 and still dominates bioethics. Critics of principlism suggest that it privileges a specific culturally rooted approach toward moral action that ignores non-Western values. Alongside these concerns over ethnocentrism came feminist critiques: scholars such as Carol Gilligan and bell hooks have attempted to bring attention to the need for a more comprehensive ethics informed by the experiences of women, people of color, and non-Western communities. While principlism still dominates global bioethics today, greater intercultural dialogue and vigorous debate have fostered greater awareness regarding the diverse landscape of ethical approaches, viewpoints, and traditions.

Computer's Social Impact

Since its creation as a tool to aid the Allied forces during World War II, the computer has transformed the social landscape, with a revolutionary impact on industry, economics, research,

communications, work, politics, leisure, and daily life.

In the late 1940s, the United States began using computers to calculate target ranges for missile guidance systems. The Semi-Automated Ground Environment (SAGE) computers that the U.S. Air Force relied on in the 1950s, produced by International Business Machines (IBM), required 20,000 square feet and weighed 300 tons. By the late 1950s, the development of integrated circuits allowed increased miniaturization, and computer technology spread into other areas by the 1960s. Incorporating integrated circuits during this time, Texas Instruments produced business calculators, and in the early 1970s the first pocket calculator. During this same period, universities, government departments, and corporations began to rely on increasingly more efficient computers. Eventually, the computer became integral to research, design, planning, management, and daily communications.

The computer's transformation of daily life was ensured in 1969, when the U.S. government's Advanced Research Project Agency (ARPA) successfully networked two computers across a considerable geographic distance, with one computer at the University of California, Los Angeles, and the other at Stanford University. By 1975, the ARPANET system connected over 60 computers in government offices and on college campuses around the nation. That same year, Micro Instrumentation and Telemetry Systems (MITS) founder Ed Roberts introduced a microcomputer kit to the public. The cost was \$395, but the peripherals needed to make it run properly were close to \$2,000. Regardless, around 2,000 units shipped out within a year. ARPANET and the MITS system solidified the foundation for the Internet and the likelihood of widespread personal computer ownership.

By 1984, around 8 percent of households in the United States had computers in them. In 1997, close to 40 percent did. By 2009, according to a study by the Center for the Digital Future at the University of Southern California, 85 percent of homes in the United States had computers, and 80 percent of its public accessed the Internet. In other developed areas of the world such as Europe, Japan, South Korea, and the Middle East, computer and Internet use also has contin-

ued to grow. Europeans' Internet use comprised 26 percent of global online activity by 2008.

The widespread use of personal computers and the Internet has influenced daily life in a multitude of ways. In developed countries, people now use personal computers for many actions that traditionally took other forms. Around 88 percent of Internet users in the United States say that they use electronic mail, known as e-mail, or instant messaging to communicate with other people. E-mail has largely replaced other forms of correspondence, such as letters, business memoranda, or transmitting faxes in business. Retail shopping now also can take place online. In fact, by 2003, 52 percent of U.S. Internet users accessed retail Web sites to purchase products or services. Banking has also begun to move online, with 28 percent of Internet users in the United States making financial transactions online in 2003. Classrooms and printed classified ads have also become less relevant, with around 25 percent of Internet users going online in 2003 for educational and job search purposes. These percentages continue to grow.

The computer has had a profound effect not only on work but also on leisure. Online networking and dating have become more popular as Web sites allow people to customize unique profiles for other people to view. Web sites allow users with high-speed broadband connections to stay at home and share information with friends, play video games, or watch movies. The production and distribution of music and film also has shifted toward the digital, transforming the entertainment industries along with publishing and news media. Traditional print media such as newspapers, periodicals, and book publishing are losing their audiences. As of 2007, about 67 percent of Internet users in the United States relied on the computer for locating news, sports, and weather information, and thus circulations for periodicals has eroded.

What has been termed a digital divide between the wealthy and poor within nations as well as between wealthy and poor nations has also emerged. In 2008, Africa, which contains 14 percent of the world's population, only had 4 percent of the world's Internet users. However, from 2000 to 2008, it did experience an Internet usage growth rate over 1,000 percent. This is due

to the rapid industrialization of rural areas and increased exposure to new technology in less-developed areas but is also due to the efforts of groups such as Collect and Recycle Ecologically (CARE), which distributes used equipment to countries such as Ghana, where less than 3 percent of the population is online.

Although clearly a source for innovation, there are concerns about the computer's social impact. While some foresaw a utopian potential of the computer to cultivate a true democracy of ideas, others have since argued that electronic and digital media deteriorate community. According to this line of argument, computers and the Internet provide people with the ability to communicate electronically, but they have decreased the amount of face-to-face contact that people experience. This may be a facile assumption. The Center for the Digital Future 2009 report notes to the contrary that Internet users in the United States report spending more time in clubs and volunteer organizations than nonusers. Other critics point to the inequalities of the digital divide, while still others express concerns about a potential loss of privacy as data about individuals, including their Web surfing habits, purchases, and e-mail correspondence may be shared and made available. Finally, computers and the Internet have also allowed old forms of social ills to increase, such as pornography and online gambling, and new forms of crime to flourish, such as Internet stalking, cyber bullying, identity theft, online confidence games, and illegal data downloading.

Brave New World— Transhumanism, Prosthesis, and Enhancement Debates

Proponents of transhumanism believe that total enhancement of human nature by technological means, including genetic manipulation and prosthetic surgery, will one day lead to a liberating posthuman condition in which our given biological state will no longer serve as a boundary of the possible. By technologically sculpting our future rather than abandoning it to evolution's reproductive roulette, we put an end to the privations of our current physical nature. Transhumanism is, conceptually, a loosely held social, philosophical, and scientific movement that has developed at the turn of the twenty-first century. Despite varying positions, transhumanism's various factions converge on the denial that the natural is in itself invaluable and not to be tampered with. Inevitably, in championing what might be regarded as the monstrous, transhumanism traces a history of controversy.

Transhumanism's overall aim is to deliver human beings from undeserved yet avoidable agony and suffering via a wholesale alteration of their bodily, mental, and even emotional abilities (e.g., affective computing), including increased longevity and rationality, the wiping out of irrational or pathological behavior, development of wholly new talents, and enhancement of levels of happiness and well-being with a view to the attainment of the perfectibility of the human species beyond strictly therapeutic boundaries. A wide gamut of future states of such perfectibility, often also described in science fiction, is foreseen and urged on, such as humans interfaced with computers, machines, or animals; fitted with prosthetic devices or neural transplantations (such as brain makers used in deep brain stimulation curing mental disorders); or even wired to a permanent exocortex system (i.e., an outside brain).

The first use of the term "posthuman" was by Francis Fukuyama, a fierce detractor who called

it the “world’s most dangerous idea.” One of the manifestos that preceded the coining of the term was roboticist Hans Moravec’s *Mind Children: The Future of Robot and Human Intelligence* (1988), which looked forward to the time when an obsolete humanity could launch its nonhuman replacements in a space colonization scheme. Human self-transcendence whereby the human body is drastically improved by artificial prosthetic members has engaged the literary imagination since ancient times, such as in the Greek myth of Icarus, and more especially in science fiction of the past century. However, the particular historical background of posthumanism, human enhancement, species change, species hybridization, transgenics, and human-machine symbiosis as these have developed in recent decades should properly be placed within contemporary techno-scientific developments.

Two crucial differences distinguish current debates from older fears induced by apocalyptic scenarios: the advanced state of converging technologies rendering such an eventuality increasingly possible (though not without certain limitations imposed by biology) and the ideology of medicalization. Technological convergence based on the systemic intertwining of a quartet of novel advanced technologies—nanotechnology, biotechnology, information technology, and cognitive science—is expected to be the driving force behind the envisaged human enhancement. The culture of medicalization likewise amounts to the dominant intrusion of medicine into all aspects of life, beyond therapy, and into cyberspace as well (with such notions as virus and antiviral), repositioning medicine at center stage and redefining, empowering, and ascribing to it new values.

Transhumanist proponents denounce old-fashioned eugenics since they advocate individual reproductive and morphological freedom on a voluntary basis uncontrolled by state and reject utopian schemes promoting ultimate plans since they support freedom of personal choice and the multiplicity of valuable modes of life. Libertarian transhumanists espouse new or laissez-faire eugenics purged from any association with the horrors of state-planned killing or enforced compulsory abortion and sterilization. Such co-

ercive practices of human breeding to improve or purify the national stock belonged to the discredited bad-science or totalitarian eugenics of the twentieth century. While transhumanists see human enhancement as an expansion of personal autonomy and reproductive choice, critics point to offsprings’ diminished autonomy and their violated right to a genetic inheritance that has not been interfered with. Genetic enhancement affects the germ line of future generations, irrevocably modifying nonpathological traits without these future beings having a chance of granting their consent.

Traditionally, arguments against transhumanism voiced by bioconservatives or religious ethicists and Bio-Luddites, or an aversion triggered by technophobia, are phrased in terms of what is considered a natural repugnance (a special “wisdom of yuck-reaction”) against designing children and against drastically altered human bodies or human-animal chimeras, as concerns over the loss of the uniqueness of human essence, or as disrespect for human dignity: the punishable hubris of playing God. Attaining full posthumanity amounts to human extinction. Further, not strictly religious or moral objections include social and political criticism targeting the possibility of increased inequalities, discrimination, and social divides as a result of enhancement, pointing to obstacles in resource allocation, curbing liberties, or mounting social pressures that leave no room for freedom of alternatives (e.g., not to enhance). Other critics predict a violent confrontation between enhanced and nonenhanced, thus warranting the appellation of transhumanists as bioterrorists.

Technology and Religion, 1945–Present

Recent scholars have argued that much religious and magical thinking surrounds the development and use of emerging technologies, regardless of how rational or scientific a technology's proponents imagine themselves. Modernity and religious thinking, rather than serving as opposites, often walk hand in hand. The idea of progress often joins religion and magic to the everyday and the technological. Modern advertisements that offer rapturous accounts of new technologies as well as science fiction depictions of utopian futures are two genres that have fostered such connections. While people with fervent religious beliefs at times have objected to new technologies, such technologies since World

War II have also supported generalized religious narratives and even engendered new religious cults.

The historian David F. Noble argued in *The Religion of Technology* (1997) that from the very onset of enthusiasm for technology, particularly in medieval monasteries, proponents such as the thirteenth-century Franciscan monk Roger Bacon imagined technology as fulfilling a religious scenario of progress. Bacon pictured technology as a path to redemption when fallen man would regain Adam's divinity and original powers. The overlap of religious with everyday conceptions of progress has continually accompanied new technologies. Historians looking at the late nineteenth century, for example, coined the phrase "technological sublime" to explain how industrial elites encouraged the public to experience technology as awe inspiring. Such an experience of the sublime might be prompted by a visit to a world's fair, by a stroll across the Golden Gate Bridge, or, more recently, by viewing a space shuttle launch or the televised shock-and-awe bombing campaign in 1990 that began the Gulf War.

The technological sublime also has blended with more apocalyptic visions of science and technology. The religious narrative of the apocalypse (common to many cultures) predicts a mythic clash between good and evil followed by the rebirth of a peaceful world. Concerns about nuclear warfare during the Cold War encouraged this apocalyptic worldview. During the Cold War, fears of impending nuclear annihilation and the Western belief that the Cold War represented a grand clash between good and evil aided Christian evangelists, such as Billy Graham in his revivalist meetings in the United States and Europe. Apocalyptic thought that focused on the rebirth of a new peaceful world also helped generate the flying saucer craze during the Cold War.

In the first six months of 1952, for example, 16,000 newspaper articles were dedicated to flying saucer sightings worldwide. In this same period, many flying saucer cults emerged in North America and Europe, helping to revitalize older occultist movements. These new religions emphasized the connection between space flight and human interaction with the heavens. In the typical flying saucer cult, a charismatic leader

Rael, the spiritual leader of the International Raelian Movement, poses before a mock spaceship in December 2002. (Clonaid/epa/Corbis)

would announce that he had experienced a vision or had channeled the voices or commands of spiritually advanced beings at large somewhere in the universe, often in flying saucers. The wise beings contacted would almost always urge world peace. There were many such groups in the 1950s, and as the millennial date of 2000 drew closer, many more such groups emerged offering millennial narratives of heavenly technological redemption.

In 1973, for example, the French race car journalist Claude Vorhilon reported encountering a flying saucer occupant who was one of the Elohim, or enlightened beings who first seeded life on earth with DNA. After this reported encounter, Vorhilon took the name Rael and founded an updated flying saucer religion, the Raelians. By 2005 the Raelian religion reported 40,000 members in France, Canada, and Japan. The Raelian Web site indicates that the religion also has members in Southeast Asia, Australia, Latin America, and Africa. The Raelians combine a fascination with such high-technology procedures as human cloning with pronouncements that a new world is imminent. The leaders of the Heaven's Gate group, a more destructive cult founded in 1975, persuaded their 39 followers to commit mass suicide in 1997 in order to be reborn on a spaceship that they believed was hidden behind the advancing Hale Bopp comet.

Throughout the twentieth century, technologists with superb credentials have also entered the millennialist arena. Rocketry and space flight pioneer Werner Von Braun, for example, became a fervent Christian who believed that spaceflight represented a fulfillment of human religious destiny. The fields of robotics and artificial intelligence have also been saturated with millennial fervor. Hans Moravec, for example, of the Robotics Institute at Carnegie Mellon University, wrote *Mind Children: The Future of Robot and Human Intelligence* (1988). His book announced that the human species was approaching obsolescence. He and other scientists, however, hoped to create a new race of mind children, robots endowed with superintelligence that would seed and redeem the universe. His book neatly fit an apocalyptic scenario of the impending ruin of a corrupt world and the birth of a cleansed post-human order.

➤ JUNG ON FLYING SAUCERS

Appearing at the height of the Cold War, Swiss psychologist Carl Jung's *Flying Saucers: A Modern Myth of Things Seen in the Skies* (1959) connected sightings of flying saucers to visionary religious experience. Jung interpreted the flying saucer as a visionary product arising from the schizophrenic political divide of the Cold War era. He proposed that the flying saucer offered a divided world a safe symbol of wholeness, perfection, and even divinity:

"Anything that looks technological goes down without difficulty with modern man. The possibility of space travel makes the unpopular idea of a metaphysical intervention much more acceptable. The apparent weightlessness of the UFOs, is, of course, rather hard to digest, but then our own physicists have discovered so many things that border on the miraculous: why should not more advanced star-dwellers have discovered a way to counteract gravitation and reach the speed of light, if not more?"

—Fred Nadis

Bibliography

C. G. Jung, *Flying Saucers: A Modern Myth of Things Seen in the Skies*, translated by R. F. C. Hull (1959; reprint, London: Routledge and Kegan Paul, 1977), 23.

These new strains of religious and millennialist thought may have been born of the stresses of maintaining a traditional religious outlook in a technological era. As in the long-running debates over the accuracy of Darwinism, religiously minded individuals and groups at times have opposed the application of new technologies. Christian fundamentalist movements and other faith-based groups have openly opposed aspects of modernity deemed threatening to the sanctity of life. For example, such groups have lobbied vigorously and effectively against aspects of abortion, cloning, and human stem cell research.

The environmentalist movements have been a more moderating influence in such culture wars centered on technology and religion. With historical roots in both scientific and religious

thought, proponents of environmentalism uphold broad principles of harmony and balance between humanity and the environment. The rise of these movements has also been accompanied on the popular level with apocalyptic warnings of impending doom. Popular accounts such as Rachel Carson's *Silent Spring* (1960) and dozens of science fiction novels and movies have featured a ruined planet. While modern concern for the environment might be traced back to 1970s' activists with progressive politics, in recent years environmentalism has also been drawing favor from religious fundamentalists. The growing Christian Environmental Stewardship movement, for example, has relied on biblical citations and teachings to encourage environmental activism.

Science and Religion, 1945–Present

Contemporary philosophers of science and religion, such as Ian G. Barbour, have argued that at any given period since the onset of the scientific revolution of the eighteenth century, different narratives of the relationship between science and religion exist, including notions of absolute conflict, of a conflict-free separation of the two spheres, and various efforts to harmonize the two categories. While recent breakthroughs in genetic engineering (such as the development of mice on which are grown human ears) raise ethical concerns and religiously inflected debate (i.e., should scientists play at “God”), the primary areas of conflict for the past century and a half have been Charles Darwin's and Alfred Wallace's theory of evolution. Evolution directly challenges and rejects a literalist interpretation of religious scripture and the biblical account of creation. Such debates have emerged frequently

in the United States and in recent decades in countries such as Russia, Poland, Australia, South Korea, and Turkey.

Often seen as the avatar of modernity, the United States, paradoxically, has been at the center of many of the major Creationist debates since the early twentieth century. At the highly dramatic Scopes Trial of 1925, a Tennessee schoolteacher was fined for teaching evolution, but the courtroom debates ridiculed the Creationist cause as hopelessly backward. Anti-Darwinism resurfaced in the U.S. political arena with laws enacted in the 1940s and again in the 1980s. The issue has not vanished. A 2001 Gallup poll revealed that only 13 percent of those polled in the United States believed in evolution, while 38 percent preferred a notion of divinely guided evolution, and 45 percent rejected evolution entirely.

In 1968 the U.S. Supreme Court struck down a 1947 Arkansas law that prohibited the teaching of evolution. The Creationist cause surfaced again, slightly modified, in the early 1980s when Arkansas passed a law requiring that Creationism be taught alongside evolution. A similar law was also passed several years later in Louisiana, leading to heated debates locally and nationally. Both laws failed to withstand court challenges. In 1999 the Kansas Board of Education approved deleting evolution from the list of subjects to be included on standardized tests, leading once again to huge public outcries and campaigns to overturn the rule. In 2000 new board members were elected in Kansas who rejected the anti-evolution rule.

Most recently, focus has shifted to the theory of intelligent design, first presented in Percival Davis and Dean Kenyon's *Of Pandas and People: The Central Question of Biological Origins* (1993). Proponents of intelligent design insist there is a scientific case to be made against entirely chance-driven evolution. This school updates the long-standing argument from design prevalent in the eighteenth and nineteenth centuries, which insists that the wonders of nature by implication indicate the hand of a designer. Proponents of intelligent design often argue that evolution can only explain modification of species but not the larger leaps to create complexity

(such as complex biochemicals or organs such as eyes) within organisms or new species. While some U.S. scientists have signed on to intelligent design, most regard it as an only slightly more sophisticated version of Creationism. The debate erupted into the legal arena in the United States when a school board in Dover, Pennsylvania, enacted a rule in 2005 requiring teachers to discuss intelligent design before teaching evolution. A court challenge once again overturned the local rule as unconstitutional.

Creationist challenges to evolution are not unique to the United States. In Turkey, despite its secularist state, Creationism and antievolution texts are gaining popularity. In Moscow, as the Soviet state weakened, a Creationist society was formed in the 1980s, circulating translations of pro-Creationist texts. In Australia in 2005, the education minister proposed that parents have the option to choose whether intelligent design be presented in classrooms. Several Christian schools began teaching the theory, leading to intense public debates akin to those in the United States.

Intelligent design has not gained ground everywhere, particularly among religious leaders who would prefer to keep science and religion in separate realms. In January 2006 the official Vatican newspaper agreed with the soundness of the court decision in Pennsylvania that rejected the requirement to teach intelligent design. A similar position was advanced by the Archbishop of Canterbury, the leader of the Anglican Church in England. In his view, religion should not be reduced to science. When asked if Creationism should be taught he replied, "I don't think it should, actually."

Outside the intelligent design debate, those seeking a more rigorous harmonization of science and religion turn to theories such as the process philosophy that British mathematician and philosopher Alfred North Whitehead offered in the early twentieth century. The process philosophy overturns a crude scientific materialism and its dichotomy between matter and mind to redefine phenomena in terms of emergent events and patterns that might more easily accord with evolution and a cosmic holism. Another key meeting place since the 1970s has been

➤ COUNCIL OF EUROPE—RESOLUTION 1580, THE DANGERS OF CREATIONISM IN EDUCATION

On October 4, 2007, the Council of Europe's Parliamentary Assembly accepted a resolution that recommends that its 47 member governments oppose teaching Creationism as science, particularly in its more refined form known as intelligent design. The resolution developed in reaction to the growing advocacy for intelligent design from various European Christian and Muslim communities to encourage its integration into national public school curriculums. Among the resolution's central recommendations are the following:

19. The Parliamentary Assembly therefore urges the member states, and especially their education authorities to:
 - 19.1. Defend and promote scientific knowledge;
 - 19.2. Strengthen the teaching of the foundations of science, its history, its epistemology and its methods alongside the teaching of objective scientific knowledge;
 - 19.3. Make science more comprehensible, more attractive and closer to the realities of the contemporary world;
 - 19.4. Firmly oppose the teaching of creationism as a scientific discipline on an equal footing with the theory of evolution and in general the presentation of creationist ideas in any discipline other than religion;
 - 19.5. Promote the teaching of evolution as a fundamental scientific theory in the school curriculums.

While merely a supranational recommendation for the 47 members of the Council of Europe, albeit with strong rhetoric, this resolution, along with similar legislation in the United Kingdom, the United States, and other states in the West, reflects the continuing schism between religious doctrines and secular scientific empiricism as advocated by Western governments. Similar to the culture wars of nineteenth-century Europe and the 1920s United States (Scopes Monkey Trial), the divide between faith and science remains central in the contemporary world.

—Abraham O. Mendoza

A school bus in Dover, Pennsylvania, passes a school board election sign in October 2005. The election would determine whether the current school board members would retain their seats, or be replaced by opponents whose platform included removing intelligent design from the science curriculum. (AP Photo/Carolyn Kaster)

environmentalism, an ethic that can be equally grounded in scientific observations or in Christian or religious theories of stewardship of nature.

Science in the Arts since 1945

Crossovers between science and art are by no means limited to the modern period. Artists have relied on principles of mathematics and physics for creating accurate representations of human proportions and perspective for centuries. In the context of the shift from the machine age to the information age in the second half of the twentieth century, the correlations between art and science became more visible than ever. Numerous artists enthusiastically embraced new media, such as light and laser projections or

video and digital imaging as well as computers and synthesizers, but they also critically pondered the detrimental effects of science and technology.

In the aftermath of World War II, people became skeptical about the modern creed of linear scientific progress. The menace of the atomic bomb weighed heavily upon human consciousness. Moreover, advances in the theory of quantum mechanics enhanced the feeling of uncertainty. Both artists and scientists increasingly reflected on the implications of their creative experiments. The Happenings organized by Allan Kaprow in the 1950s emphasized temporal relativity, chance, and spontaneous behavior. Spectators were invited to directly participate in loosely scripted events by manipulating a variety of props in imaginative ways.

Norbert Wiener's theory of cybernetics (a mathematical approach to communication and information flow) formulated in 1948 catalyzed artists' interest in framing creative processes and events that encouraged human-machine interaction. In the second half of the 1950s, Nicolas Schöffer staged spatiodynamic spectacles in which cybernetic sculptures mechanically rotated and changed configuration in relation to human movement and light and sound variations. The members of GRAV (Groupe de Recherche d'Art Visuel), an art group active in Paris in the 1960s, were equally fascinated by the disruptive effect of kinetic environments. They were intent on annihilating the distance between spectators and art objects by creating technology-based labyrinths in outdoor settings that responded to the movements of passers-by.

Yet this enchantment with the new expressive possibilities inspired by cybernetics was sometimes tinged with anxiety over the close relationship between science and military applications. Fighting against the denigration of technology in Germany after the war, artist Otto Piene highlighted the role that art could play in appeasing fears of bombardments. Together with Franz Mack, he established Group Zero in Düsseldorf in 1957. They organized sublime light projections by relying on both technological equipment and natural factors, such as wind and water movement. In spite of the fact that they were somewhat reminiscent of air raids, these

events were supposed to have a therapeutic role and encourage experimentation. Swiss artist Jean Tinguely's self-destructive machine-sculptures constructed in the 1960s with the help of engineers also betrayed artists' ambivalent position toward scientific experimentation. The spectacular collapse of Tinguely's machines after a series of more or less intended malfunctions showed that technology cannot be perfectly controlled. It also seemingly announced the end of the machine era.

Influenced by cybernetics and new technologies, artists turned to new conceptual approaches that treated images and viewers as information. Les Levine, Frank Gillette, and Ira Schneider used closed-circuit television to encourage viewers to manipulate their self-image and see themselves in relation to others. Instead of focusing on the material shape of things, many artists called attention to biological, physical, and social processes that undermined the stability and permanence of the art object. In the 1960s, David Medalla constructed boxes that spit out dense waves of foam, Robert Barry released inert gases in the atmosphere as part of a publicized art project, and Hans Haacke displayed Plexiglas cubes filled with a small amount of water that would condense and form intricate patterns of drops. Many of these artists have relied as much on natural processes as on technological means to reveal the entropic transformations of systems. To respond to such challenges, engineer Billy Klüver and artists Robert Rauschenberg and Robert Whitman founded the collective Experiments in Art and Technology (E.A.T.) in 1966. The group had the role of assisting artists in finding appropriate electronic devices for making their ideas take shape.

The staging of environments that offer virtually unlimited possibilities of interaction has remained the desideratum of artists up to the present. In the 1970s, Myron Krueger designed computerized environments that responded to participants' actions in unexpected ways, and Lynn Hershman created the first interactive video installation based on laser disk technology that allowed participants to construct a story out of film sequences of their own choice. The Internet and open-source databases have granted new opportunities for designing real and virtual spaces

➤ THE PEPSI PAVILION, OSAKA, 1970

At the time of the Osaka World Expo of 1970, PepsiCo, the soft drink company, aimed to attract younger audiences by constructing a dome-shaped pavilion where rock concerts could be organized. The budget turned out to be too low for this purpose. After considering a series of alternatives, PepsiCo. commissioned E.A.T. (Experiments in Art and Technology) to design the interior of the pavilion and stage a series of performances. Acting as a group, the E.A.T. members hoped to negotiate with the corporation more easily. Over 70 artists, engineers, and consultants were involved in the project. As the executive coordinator of the Pepsi Pavilion, engineer Billy Klüver asked contributors to adopt a well-delimited role in the design process. Fujiko Nakaya explored several techniques for enveloping the pavilion in a veil of fog, Forrest Meyers designed exterior xenon projections, Robert Breer constructed mobile sculptures that slowly meandered on the pavilion terrace, Robert Whitman suggested creating a mirror dome inside the pavilion to generate holographic reflections, and David Tudor set up several acoustic channels to transmit sounds of varying frequency to different parts of the dome. Within the Pepsi Pavilion, visitors virtually lost sense of the material boundaries of their bodies. The compelling visual effects engendered by the reflective environment were paralleled by complex tactile and audio stimuli. With the help of a programming console, artists created audio-visual events in conformity with a pre-established program. E.A.T. members viewed the Pepsi Pavilion as a metaphor of the human mind, a mirrorlike surface that responded to sensorial impulses and affected the behavior of participants.

—Cristina Albu

that enable creative multiuser participation. Artists Paul Sermon, Julia Scher, and Rafael Lozano-Hemmer use technological interfaces to explore affective perceptual processes, bodily relations, and intimate encounters between people found in distant locations. While these artists contemplate the democratic potential of virtual networks, they also critically address issues of surveillance, control, and privacy.

Scientists and engineers continue to explore the parallels between electronic networks, biological networks, and ecosystems. While engineers currently resort to biological modeling to increase the efficiency of information dissemination, artists such as Chu-Yin Chen and Gina Czarnecki create environments in which viewer interaction activates virtual models of cell growth patterns and the spread of viruses. Contemporary scientific research and art practice reveal the advantages and risks implicit in living in a highly networked world.

What Is World History?

Alfred J. Andrea and Carolyn Neel

Our purpose in creating this massive work, the *World History Encyclopedia*, is to provide intelligent laypeople, teachers, and students with a resource that will allow them to reach an understanding of the world in which they live. We offer a perspective that we believe will serve them well as they grapple with today's events and attitudes. First and foremost, we hope to assist them in developing a vision of the world as a human habitat, full of creativity, beauty, cooperation, brutality, choices, aptitudes, and attributes. We emphasize that a linear series of national, cultural, or geographical histories may have been considered world history in the past but is no longer a valid approach. Those elements are simply pieces of a mosaic designed to allow us to examine our world.

World history is as old as the putative “fathers of history,” Herodotus (fl. 450 BCE), Sima Qian (d. after 91 BCE), and the authors of Genesis. Each attempted to place the history of a particular people—Greeks, Chinese, and Israelites—into a far larger context, the context of the world as he knew and understood it. Beginning in the latter half of the twentieth century, however, a new historiographical tradition emerged, known as the New World History. Contemporary enthusiasm for world history, which is fast becoming global, initially blossomed in the United States in the aftermath of World War II and the Cold War that followed. People in the United States realized that isolationism was no longer possible or desirable. Consequently, interest in learning about other cultures and the interactions between societies led to an increasing interest in the study of world history. Such curiosity intensified as U.S. citizens realized, with some apprehension, that the “national” finances of the great American economic giant were intertwined with a global economic system. Three other phenomena were also at work. Demographically and culturally, the United States was clearly becoming far more complex and variegated after 1945, as immigrants from all over the globe swelled its numbers and enriched its social fabric. No longer was the standard Euro-American history a satisfactory response to the

question, “What are our roots?” With increased prosperity, higher levels of general education, greater leisure time, and faster modes of intercontinental travel, Americans were on the road to foreign destinations in numbers that multiplied almost annually, adding significantly to a growing awareness of and interest in the cultures of once-distant peoples. Then there was television and the other media of mass and fast communication that followed. Not only were Americans now able to view in their homes the cultures and histories of societies that once were largely unknown to the average university-educated American, but American culture was also going global and often returning to the United States in altered but interesting ways. One of many such manifestations of this development, which especially captivated young people, was (and is) Afropop, a blend of traditional African melodies and forms with Western music (much of which, in turn, had earlier connections with the music of Africa).

Most historians—certainly those who consider themselves students, consumers, or producers of works on world history—agree that this accelerating interest has been and will continue to be a good thing. Indeed, those who devote their lives to the discipline tend to be evangelical; some even believe that humanity’s very survival as a species depends upon our developing a nuanced understanding of the history of the world in which we live.

The discipline’s enthusiasts only begin diverging when they define their interests and methods of research and teaching. All agree on one issue. World history is *not* a collection of national or regional histories studied one after another. Put briefly, world history is a study of the past that transcends or crosses national, regional, and cultural boundaries. World history is also not, and can never be, the history of everything that has ever happened everywhere in the world. In order to be coherent and comprehensible, our remembrance, or reconstruction, of the past must be ordered and assembled with an end in mind. As is true of all historians no matter their specialty, world historians begin with specific questions and working hypotheses and subject those questions and hypotheses to exacting examination through careful analysis of available evidence. Only then do they venture to offer insights and to write their narratives. The only difference between the historian who focuses on a single nation, region, or cultural phenomenon and a world historian is the scope of the question and the narrative that follows.

When considering world history in the context of the discipline as a whole, it helps to think of a photographer in the field who carries a variety of lenses for a single camera. Some of those lenses are telescopic, allowing the photographer to capture distant objects. Others magnify minute objects that are close at hand but indistinct in their details to the unaided eye. Still others, known as wide-angle lenses, allow the photographer to take in vast panoramas. World history is analogous to that wide-angle lens.

The vast panoramas that world historians seek to describe include, but are not limited to, such issues as the ways in which societies across the world have come into contact with one another and cross-fertilized through a process of cultural interchange and adaptation. They also in-

clude a comparative, almost anthropological, approach to the past in which world historians study the different ways that diverse and often unconnected cultures have responded to similar stimuli. In addition to these three Cs—contact, cultural exchange, and comparative analysis—world historians are vitally interested in the ways in which societies across the globe have both cooperated and been in conflict with one another. One area in this regard that has become a rich field of inquiry for the new world historians is the study of borders and frontiers and the ways in which various societies have carried on complex relationships with their neighbors. Consider China, the self-described “Central Country” or “Middle Kingdom,” that has had a complex series of relationships with the many “peripheral” cultures along its borders. It is no wonder that China’s foreign relations loom large as a field of study for world historians. Simply put, world historians focus on historical *connections* on a grand scale. As already implied, that scale does not have to be global. For example, long-distance exchange of commodities and ideas along trade routes in the pre-Columbian Americas or similar commerce throughout Afro-Eurasia before 1500 CE have proved to be fruitful areas of investigation for many world historians.

Paradoxically, study of such grand vistas as, for example, exchange along the Silk Roads has also made world historians aware of the importance of many areas and cultures that were once considered obscure, largely peripheral to “real history,” and the province of only a few eccentric specialists working on arcane topics. One such area that is increasingly assuming a prominent position in world history studies is central Asia. No longer can it be seen as a great expanse of wasteland peopled only by nomadic pastoralists whose sole significant role in history was to occasionally raid and even overturn the states that ringed these great steppe lands, mountain ranges, and deserts that stretched from the Black and Caspian seas to Manchuria. To the contrary, the peoples, cultures, states, and even empires of central Asia are now coming into clearer focus (remember the historian as photographer?) and are being recognized for what they have been for many millennia: driving forces in the history of Afro-Eurasia.

Another paradox of world history studies is that the great majority of world historians, almost all in fact, also specialize in some discrete area of history. Most use their special area of interest, such as Tang China (618–907 CE), as a starting point for their world history studies. These two perspectives complement one another and result in a richer and fuller picture of both the localized field of inquiry (Tang China) and the broader field of study (Afro-Eurasia in the seventh and eighth centuries). To reiterate: all of the pieces are important, but they become world history only when assembled into the grand mosaic.

Preface: This World History Encyclopedia

Alfred J. Andrea and Carolyn Neel

We live in an exciting and complex world. The realization that we are interlinked with other countries economically, politically, and culturally has inspired us—as curious laypeople, entrepreneurs, concerned citizens, or academics—to search for greater understanding of societies with which we share this globe. We find the process of globalization alternately exciting and disturbing, depending on the events of the day and our individual convictions. This intensified concern with international connections inspired educators to develop core courses in world history, some in response to state directives. Instructors by and large embrace the task, yet these mandates necessitate broad resources. Our goal for the *ABC-CLIO World History Encyclopedia (WHE)* has been to provide an interesting and comprehensive resource that is accessible to the intelligent reader, whether layperson, student, or instructor. We wanted to promote a deeper understanding without assuming prior knowledge. We were determined to write plainly and avoid jargon but never to “write down” or oversimplify. History presents many unanswered questions, and good history writing must address the past’s ambiguities and uncertainties. We also embraced the necessity for historical truth by addressing the common distortions in our understanding of history sometimes introduced in more or less well-meaning attempts to encourage pride by inflating the nobility, wisdom, or status of our ancestors.

The *WHE* is the result of several big dreams, beginning in early 2002, in the minds of Ron Boehm, the CEO of ABC-CLIO, and Simon Mason, an ABC-CLIO acquisitions editor. Simon searched for an academic general editor who shared his vision of a comprehensible story of human history. After an extensive search, he recruited Al Andrea during the spring of 2003, and Al came on board in January 2004. Although Simon went on to address other challenges, we believe that the encyclopedia remained true to his vision. His proposal remained our basic founding document and inspiration. By the summer, the team began to jell. Carolyn Neel was

hired as project editor in October 2004, and that month Carolyn, Ron, and Al began working together in earnest to refine the design of the *WHE*. Al had already been recruiting era editors to manage the nine chronological periods that the work would cover. He enticed Wilfred (Fred) Bisson, William (Bill) Mierse, James Overfield, Dane Morrison, and Micheal Tarver early on, reserving one era, the fifth (1000–1500) for himself. Later, Al and Carolyn were able to convince Kevin McGeough, Jack Waskey, Mark Aldenderfer, Fred Nadis, and, after the project was under way, Alexander Mikaberidze who joined us later in heroic effort to bring the *WHE* to the finish line.

We began organizing our project. Early on we had realized that the rich complexity of world history does not allow for a standard A–Z organization of entries. Such a structure plays havoc with the concept of change over time and would confuse more than enlighten. We also knew from many years of teaching that organizing world history courses under strict chronological narratives does not work well. There is too much happening simultaneously in too many parts of the world. The story becomes lost in a rapid blur of dates, names, and event. Yet chronology is the basic metric that every historian must follow. B does not happen before A and cannot, in Whiggish fashion, be read back into the past. Whether we like it or not, the discipline forces us to construct chronological narratives. For that reason, historians have traditionally divided the past into coherent periods, or eras, and have provided them with titles, such as the “Age of Democratic Revolutions.” These categorizations have a useful purpose in that they tend to focus attention on specific aspects of the past rather than presenting a confetti of dates, places, and strange names. Unfortunately, these labels also predispose us—professionals as well as students—to look at periods of time through a preset conceptual lens, often blinding us to phenomena that run counter to the theoretical overlay. For example, a student exploring the world through the perspective of western Europe’s so-called Scientific Revolution might miss the reality that societies in this same era experienced a widespread efflorescence of emotional religious or romantic movements throughout Europe and the Americas. World history presents the would-be codifier of eras with an almost insoluble conundrum. How does one find a characterization to describe a period of time that would be historically valid across the world? After all, even in the twentieth century societies across the globe are confronted with different challenges and move at different paces.

Over the past 50 years, many creative schemas have evolved. Fortunately, if we took great care to emphasize to our readers that these arbitrary delineations were for conceptual convenience, not indicators of concrete global realities, the task had already been largely done for us. As Simon Mason pointed out in his proposal, in 1994 the National Center for History in the Schools, under Professor Ross Dunn of San Diego State University, developed a set of national standards for world history for grades 5–12. Those standards had sadly fallen victim to political controversy but were widely respected by historians. Realizing that periodization of world history was absolutely necessary despite its pitfalls, Dunn and his collabo-

rators devised a schema comprised of eight eras that, in our estimation, was sufficiently general and broadly valid as to work fairly well. They are Era 1, The Beginnings of Human Society; Era 2, Early Civilizations to 1000 BCE; Era 3, Classical Traditions, Major Religions, and Giant Empires, 1000 BCE–300 CE; Era 4, Expanding Zones of Exchange and Encounter, 300–1000 CE; Era 5, Intensified Hemispheric Interactions, 1000–1500 CE; Era 6, Emergence of the First Global Age, 1450–1770; Era 7, The Age of Revolutions, 1750–1914; and Era 8, The Twentieth Century. This was an excellent beginning, but we needed to slightly refine this “table of historical periods” in light of our twenty-first-century purposes and perspectives. Again, with Simon’s proposal as our guide, we decided on a nine-part structure: Era 1, Beginnings of Human Society to 4000 BCE; Era 2, Early Civilizations, 4000–1000 BCE; Era 3, Classical Traditions, 1000 BCE–300; Era 4, Expanding Regional Civilizations, 300–1000 CE; Era 5, Intensified Hemispheric Interactions, 1000–1500; Era 6, The First Global Age, 1450–1770; Era 7, The Age of Revolutions, 1750–1914; Era 8, Crisis and Achievement, 1900–1945; and Era 9, Promises and Paradoxes, 1945–present.

Despite these nine eras that serve as the encyclopedia’s most basic divisions, it made sense to us (and again, Simon’s initial vision was our guideline) to organize the eras along thematic lines. As already noted, it is not feasible to try to give a simultaneous account of every society in the world; students and instructors alike would drown in a sea of facts.

We turned again to the National Standards for World History, which calls for the development of five themes: social, political, scientific/technological, economic, and cultural (philosophical/religious/aesthetic). Recognizing current historiographical trends and anticipating future developments, in full consultation with the era editors, Al and Carolyn went a bit further, and we wound up with eight themes: (1) Population and Environment, (2) Society and Culture, (3) Migration and Travel, (4) Politics and Statecraft, (5) Economics and Trade, (6) War and Diplomacy, (7) Thought and Religion, and (8) Science and Technology. Each theme would be further divided into major topics, and each topic would be developed through short essays ranging in length from 600 to 2,000 words, depending on the significance of the item under discussion, and almost every essay entry would be accompanied by a sidebar (short secondary articles highlighting some aspect of the main essay). For example, under Theme 2, Society and Culture, a topic might be literature across the world in the period between 1000 and 1500. Essays under the topic might then deal with literature in Persia, Tamil India, Islamic India, Southeast Asia, Japan, China, Latin Europe, Byzantium, the Inca empire, and other significant areas of the world. Sidebars would be designed to put the human face on each entry, perhaps a passage from a Chinese poem, an example showing the role of troubadours in Europe, and so forth. In the process of commissioning desired essays, we often found ourselves with a nice variety of regional examples, with accompanying human-interest sidebars, but discovered that we still needed an overview essay to tie them together. Given that reality, we quickly realized that we would need thematic and topic introductions to tie the pieces together into a “world history” perspective.

Early on, the question of “voice” arose. Would we try to maintain a single voice across the eras, or would we embrace the “multiple voices” mode of presentation? Al, Ron, and Carolyn agreed that much of the joy and beauty of studying world history comes from lively exchanges—a multiplicity of voices and perspectives—both in the primary source materials and in the work of those who compile histories. We believed that an attempt at a uniform voice would dilute the representation of people from various social and economic levels, various genders, and differing cultural milieus. Trying to force everything into one narrative tone would strip away much of the richness. And, of course, there was always the issue of the “adopted voice.” Historians tend to take on the cadence and vocabulary of those whom they spend their lives studying. We wanted to preserve those voices from the present and the past. The many-voices decision enriched the encyclopedia in ways that we had not originally anticipated because it allowed scholars to write from their hearts as well as their intellects. History without passion is sterile.

So, having developed the basic philosophy behind the structure of the work, Al and Carolyn spent a long week in a Santa Barbara conference room discussing, arguing, shifting sides, revising, evaluating. How would we deal with uneven coverage of themes? For instance, in the era 1500–1750, there were many developments in the ways humans conceive the divine or transcendent—whole libraries have been built with worthwhile works on the topic—but how much can we deduce about religious (or any other) sentiments in the period from the first hominids until about 3500 BCE? We look at evidence and draw conclusion, but the conclusions are based on our own worldviews; the minds of the earliest humans are out of our reach. But wait. Educated speculations based on archaeological remains are worth considering, and perhaps “what we don’t know” is indeed as important as “what we do.” It was a stimulating, invigorating, and exhausting week. At its end, Al and Carolyn realized that there was much to say about every theme in every corner of the world in every era, but trying to impose an artificial consistency for the relative percentage devoted across eras to any theme would result in distortions. We decided to avoid inflating or flattening any theme’s percentage of the era’s total number of words just to maintain a proportional consistency.

The next week we refined our notes and sent them to the era editors, asking for outlines for their eras, structured around the skeleton we had developed. As they came in we analyzed them, looking at the percentage of the proposed text devoted to each theme, and found that instinctively the era editors had made appropriate adjustments; not all themes are equally important in all ages. For instance, Era 5 (1000–1500) might devote a bit larger percentage of copy to disease because of the Great Eurasian Pandemic (known in the West as the Black Death), which began in China about 1330 and spread across Europe in the period 1348–1350. Era 7 (1750–1914), on the other hand, which encompasses the Industrial Revolution, might spend a higher percentage on the impact of technology. Not all issues had the same importance across all eras.

We began a series of long bimonthly teleconferences, most attended by all of the era editors, refining our approach. Each conversation lasted for more than two hours until one of us would throw in the towel by

admitting that his or her head was about to explode, and we would schedule the next one. Questions arose, and we found good answers for most, superb answers to a few, and agreed to revisit others. An example: Fred Bisson, editor of *Era 4* (300–1000 CE), asked where we would situate essays on warfare. The social impact of war would logically fit under “Society and Culture”; technological and scientific changes or discoveries made during the effort to provide weapons of war went under “Technology and Science.” But where would narratives of specific wars and war leaders fit? Of course they would normally go under the heading “War and Diplomacy,” but we would have to be very careful to ensure that the war did not overwhelm entries about efforts at diplomatic solutions. The biweekly teleconferences continued for several months, then Al and Carolyn met again in Santa Barbara to sort through the outlines. We commandeered a conference room and pasted copies of the outlines around the space at eye level (Carolyn’s eye level, as tiptoeing is more difficult than bending a bit).

By the end of July 2005, we believed that the work was as well designed as was humanly possible. Nearly every aspect of human life through nearly the whole of human existence was at least touched upon if not fully covered. We looked for thematic examples across the world, from the development of earliest humanoids to the age of astronauts, from the northernmost settlements in Russia, Siberia, or Canada to the southernmost areas of South America and the semipermanent stations of Antarctica. The work was organized so that readers could trace one aspect of human history, such as women’s roles, throughout history; they could make direct comparisons of changes brought about by temporal, cultural, or geographic distance or any combination thereof. By reading any one theme throughout the various eras, readers could develop a deep understanding of an issue, such as changes in environment and population or in attitudes toward technology. Teachers could assign the era introductions to a class to help students get a big-picture view of the topics to be covered in a class. There were so many ways to sort and pursue their interests that we began thinking about creative ways of organizing the search functions on the electronic versions.

We basked in the sheer beauty of our design; actually, we spent a couple of hours basking. Now all we had to do was find folks to write it all up. And therein lay the problem. The will was there with many scholars. We had a very good response from postings in *H-World* and e-mail notes to colleagues at university history and anthropology departments. But in some areas, the scholarship just did not exist yet. In other areas, scholars simply had so many other commitments that they had no time to devote to this project. We struggled with Africa—plenty of great African scholars around—but many were booked up for the next two or three or ten years. We found three outstanding scholars who made time to work with us—Candice Goucher, Jonathan Reynolds, and Eric Gilbert—and eventually they either wrote the entries we needed or found colleagues to do so. But entries on more comparative topics, such as comparing economic conditions in eleventh-century southern Asia with those in Europe, were beyond our reach. Over the next year we realized that few scholars were comfortable doing broad comparisons. Many of

our entries—essays under a single topic—would be centered on specific parts of the world, perhaps one on India, one on Germany, one on the Incas, one on Japan. But as already anticipated, we needed to have a solid topic introduction to tie them together into a world history perspective by making explicit comparisons and looking at the broader view. Composing these topic introductions fell largely to the era editors, and it was a task that proved formidable but doable after much gnashing of teeth.

Not surprisingly, we also found that many of the most exciting entries were done by a contributor/editor team when young scholars—sometimes advanced graduate students—were paired with academic editors with longtime experience in their fields. The back-and-forth (or, even often push-pull) relationships produced fresh insights that were well anchored to a solid base of acceptable historiography. We had a sense of insight and adventure interspersed with exhaustion. Some days it seemed that it would never be done; other days the finish line seemed to be just ahead.

The *WHE* team grew both at ABC-CLIO and in the number of people who were willing to invest their time and expertise in the project. The era editors have been the finest, most collegial group possible and made the work a joy despite some frustrating times. The ABC-CLIO staff's names are listed in the front of this volume. Each brought a set of characteristics and abilities that kept the work exciting. The *WHE* could never have reached this point without the grace, intelligence, and dedication of the entire staff both editorial and the fine production staff under the guidance of Donald Schmidt, a gentleman and scholar himself. We also owe a special note of gratitude to many fine contributors such as William Burns, who hung in with us throughout the entire project. And Al and Carolyn want to add a special note of thanks to Ron Boehm, who pushed, prodded, and challenged but never lost faith in us, even when we ourselves felt on shaky ground. All in all it has been a wonderful experience, and we did in fact live through it.
